Proposal for:

Business Process Model and Notation (BPMN)
Specification 2.0

V0.9.14
(revised submission draft)
May 22, 2009

In response to: Business Process Model and Notation RFP (OMG Document bmi/2007-06-05)

Submission Team

OMG Submitters
Axway
International Business Machines
MEGA International
Oracle
SAP AG
Unisys

Co-Authors
BizAgi
Bruce Silver Associates
IDS Scheer
Model Driven Solutions
Software AG
TIBCO Software
The following companies provided valuable review, feedback and support:

Accenture
Active Endpoints
Adaptive
Capgemini
Enterprise Agility
France Telecom
Insubria University
Intalio
Metastorm
Nortel
Red Hat Software
Vangent

Permission to copy, display, perform, modify and distribute the Business Process Model and Notation (BPMN) 2.0 Specification (the “Specification”, which includes WSDL and schema documents), and to authorize others to do the foregoing, in any medium without fee or royalty is hereby granted for the purpose of developing and evaluating the Specification.

Axway, BizAgi, Bruce Silver Associates, IDS Scheer, International Business Machines, MEGA International, Model Driven Solutions, Oracle, SAP AG, Software AG, TIBCO Software and Unisys (collectively, the “Authors”) each will grant a license to third parties, under royalty-free and otherwise reasonable, non-discriminatory terms and conditions, to their respective essential patent claims that they deem necessary to implement the Specification.

Proposal for:
Business Process Model and Notation (BPMN), v2.0
DISCLAIMERS:

THE SPECIFICATION IS PROVIDED "AS IS," AND THE AUTHORS MAKE NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, NON-INFRINGEMENT, OR TITLE; THAT THE CONTENTS OF THE SPECIFICATION ARE SUITABLE FOR ANY PURPOSE; NOR THAT THE IMPLEMENTATION OF SUCH CONTENTS WILL NOT INFRINGE ANY THIRD PARTY PATENTS, COPYRIGHTS, TRADEMARKS OR OTHER RIGHTS.

THE AUTHORS WILL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF ANY USE OF THE SPECIFICATION OR THE PERFORMANCE OR IMPLEMENTATION OF THE CONTENTS THEREOF.

You may remove these disclaimers from your modified versions of the Specification provided that you effectively disclaim all warranties and liabilities on behalf of all copyright holders in the copies of any such modified versions you distribute.

The name and trademarks of the Authors may NOT be used in any manner, including advertising or publicity pertaining to the Specification or its contents without specific, written prior permission. Title to copyright in the Specification will at all times remain with the Authors.

No other rights are granted by implication, estoppel or otherwise.

- Proof of Concept
- Typographical Conventions
- Guide to the submission

Submitting Organizations

The following companies are formal submitting members of OMG:

- Axway
- International Business Machines
- MEGA International
- Oracle
- SAP AG
- Unisys

Supporting Organizations

The following organizations support this specification but are not formal submitters:

- Accenture
- Adaptive
- BizAgi
- Bruce Silver Associates
- Capgemini
- Enterprise Agility
- France Telecom
- IDS Scheer
- Intalio
• Metastorm
• Model Driven Solutions
• Nortel
• Red Hat Software
• Software AG
• TIBCO Software
• Vangent

Submission Contacts
Martin Chapman, Oracle, martin.chapman@oracle.com
Dave Ings, IBM, ings@ca.ibm.com
Ivana Trickovic, SAP, ivana.trickovic@sap.com

Acknowledgements
The following persons were members of the core teams that contributed to the content specification: Anurag Aggarwal, Mike Amend, Sylvain Astier, Alistair Barros, Mariano Benitez, Conrad Bock, Martin Chapman, Rouven Day, David Frankel, Dave Ings, Pablo Irassar, Oliver Kieselbach, Matthias Kloppmann, Jana Koehler, Frank Michael Kraft, Frank Leymann, Antoine Lonjon, Sumeet Malhotra, Jeff Mischkinsky, Ralf Mueller, Karsten Ploesser, Michael Rowley, Suzette Samoojh, Vishal Saxena, Bruce Silver, Meera Srinivasan, Ivana Trickovic, Hagen Voelzer, Franz Weber, and Stephen A. White.

In addition, the following persons contributed valuable ideas and feedback that improved the content and the quality of this specification: Justin Brunt, Peter Carlson, Manoj Das, Sumeet Malhotra, Neal McWhorter, Vadim Pevzner, Pete Rivett, Jesus Sanchez, Sebastian Stein, and Prasad Yendluri.

Status of the Document
This document is an initial specification for review and comment by OMG members.

IPR and Patents
The submitters intend to contribute this work to OMG on a RF on RAND basis.

Typographical Conventions
The type styles shown below are used in this document to distinguish programming statements from ordinary English. However, these conventions are not used in tables or section headings where no distinction is necessary.

Times/Times New Roman - 11 pt.: Standard body text
Verdana – 11 pt.: Key BPMN elements
Proof of Concept

The submitters of this specification have extensive experience in building business process management tools and in implementing previous versions of the Business Process Modeling Notation specification. This specification incorporates experience the submitters have gained so far and includes proven design principles. Proof of concept implementations for this version have started and will continue in parallel with the FTF work.

Responses to RFP Requirements

See Annex A.

Guide to the Submission

The submission is organized into the following sections: Those sections are normative that are indicated as such, below.
1. Scope

The Object Management Group (OMG) has developed a standard Business Process Modeling Notation (BPMN). The primary goal of BPMN is to provide a notation that is readily understandable by all business users, from the business analysts that create the initial drafts of the processes, to the technical developers responsible for implementing the technology that will perform those processes, and finally, to the business people who will manage and monitor those processes. Thus, BPMN creates a standardized bridge for the gap between the business process design and process implementation.

Another goal, but no less important, is to ensure that XML languages designed for the execution of business processes, such as WSBPEL (Web Services Business Process Execution Language), can be visualized with a business-oriented notation.

This specification represents the amalgamation of best practices within the business modeling community to define the notation and semantics of Collaboration diagrams, Process diagrams, and Choreography diagrams. The intent of BPMN is to standardize a business process modeling notation in the face of many different modeling notations and viewpoints. In doing so, BPMN will provide a simple means of communicating process information to other business users, process implementers, customers, and suppliers.

The membership of the OMG has brought forth expertise and experience with many existing notations and has sought to consolidate the best ideas from these divergent notations into a single standard notation. Examples of other notations or methodologies that were reviewed are UML Activity Diagram, UML EDOC Business Processes, IDEF, ebXML BPSS, Activity-Decision Flow (ADF) Diagram, RosettaNet, LOVeM, and Event-Process Chains (EPCs).

2. Conformance

Software may claim compliance or conformance with BPMN 2.0 if and only if the software fully matches the applicable compliance points as stated in the specification. Software developed only partially matching the applicable compliance points may claim only that the software was based on this specification, but may not claim compliance or conformance with this specification. The specification defines four types of conformance namely Process Modeling Conformance, Process Execution Conformance, BPEL Process Execution Conformance and Choreography Modeling Conformance.

The implementation claiming conformance to Process Modeling Conformance type is not required to support Choreography Modeling Conformance type and vice-versa. Similarly, the implementation claiming Process Execution Conformance type is not required to be conformant to the Process Modeling and Choreography Conformance types.

The implementation claiming conformance to the Process Modeling Conformance type shall comply with all of the requirements set forth in Section 2.1. The implementation claiming conformance to the Process Execution Conformance type shall comply with all of the requirements set forth in Section 2.2. The implementation claiming conformance to the BPEL Process Execution Semantics Conformance type shall comply with all of the requirements set forth in Section 2.3. The implementation claiming conformance to the Choreography Conformance type shall comply with all of the requirements set forth in Section 2.4. The implementation is said to have BPMN Complete Conformance if it complies with all of the requirements stated in Sections 2.1, 2.2, 2.3, and 2.4.

Proposal for: Business Process Model and Notation (BPMN), v2.0
2.1. Process Modeling Conformance

The next eight (8) sections describe Process Modeling Conformance.

2.1.1. BPMN Process Types

The implementations claiming Process Modeling Conformance must support the following BPMN packages:

- The BPMN core elements, which include those defined in the Infrastructure, Foundation, Common, and Service packages (see page 70).
- Process diagrams, which include the elements defined in the Process, Activities, Data, and Human Interaction packages (see page 153).
- Collaboration diagrams, which include Pools and Message Flow (see page 143).
- Conversation diagrams, which include Pools, Communications, and Communication Links (see page 328).

2.1.2. BPMN Process Elements

The Process Modeling Conformance type set consists of Collaboration and Process diagram elements, including all Task types, embedded Sub-Processes, CallActivity, all Gateway types, all Event types (Start, Intermediate, and End), Lane, Participants, Data Object (including DataInput and DataOutput), Message, Group, Text Annotation, Sequence Flow (including conditional and default flows), Message Flow, Conversations (limited to grouping Message Flow, and associating correlations), Correlation, and Association (including Compensation Association). The set also includes markers (Loop, Multi-Instance, Transaction, Compensation) for Tasks and embedded Sub-Processes.

Note: Implementations are not expected to support Choreography modeling elements such as Choreography Task and Choreography Sub-Process.

2.1.3. Visual Appearance

A key element of BPMN is the choice of shapes and icons used for the graphical elements identified in this specification. The intent is to create a standard visual language that all process modelers will recognize and understand. An implementation that creates and displays BPMN Process Diagrams shall use the graphical elements, shapes, and markers illustrated in this specification.

Note – There is flexibility in the size, color, line style, and text positions of the defined graphical elements, except where otherwise specified (see Page 63).

The following extensions to a BPMN Diagram are permitted:

- New markers or indicators MAY be added to the specified graphical elements. These markers or indicators could be used to highlight a specific attribute of a BPMN element or to represent a new subtype of the corresponding concept.
- A new shape representing a kind of Artifact may be added to a Diagram, but the new Artifact shape SHALL NOT conflict with the shape specified for any other BPMN element or marker.
• Graphical elements may be colored, and the coloring may have specified semantics that extend the information conveyed by the element as specified in this standard.

• The line style of a graphical element may be changed, but that change SHALL NOT conflict with any other line style required by this specification.

• An extension SHALL NOT change the specified shape of a defined graphical element or marker. (e.g., changing a square into a triangle, or changing rounded corners into squared corners, etc.).

2.1.4. Structural Conformance

An implementation that creates and displays BPMN diagrams shall conform to the specifications and restrictions with respect to the connections and other diagrammatic relationships between graphical elements. Where permitted or required connections are specified as conditional and based on attributes of the corresponding concepts, the implementation shall ensure the correspondence between the connections and the values of those attributes.

Note – In general, these connections and relationships have specified semantic interpretations, which specify interactions among the process concepts represented by the graphical elements. Conditional relationships based on attributes represent specific variations in behavior. Structural conformance therefore guarantees the correct interpretation of the diagram as a specification of process, in terms of flows of control and information. Throughout the document, structural specifications will appear in paragraphs using a special shaped bullet:

Example: • A TASK MAY be a target for Sequence Flow; it can have multiple incoming Flows. An incoming Flow MAY be from an alternative path and/or parallel paths.

2.1.5. Process Semantics

This specification defines many semantic concepts used in defining Processes, and associates them with graphical elements, markers, and connections. To the extent that an implementation provides an interpretation of the BPMN diagram as a semantic specification of Process, the interpretation shall be consistent with the semantic interpretation herein specified. In other words, the implementation claiming BPMN Process Modeling Conformance has to support the semantics surrounding the diagram elements expressed in Section 10.

Note – The implementations claiming Process Modeling Conformance are not expected to support the BPMN execution semantics described in Section 14.

2.1.6. Attributes and Model Associations

This specification defines a number of attributes and properties of the semantic elements represented by the graphical elements, markers, and connections. Some of these attributes are purely representational and are so marked, and some have required representations. Some attributes are specified as mandatory, but have no representation or only optional representation. And some attributes are specified as optional. For every attribute or property that is specified as mandatory, a conforming implementation SHALL provide some mechanism by which values of that attribute or property can be created and displayed. This mechanism SHALL permit the user to create or view these values for each BPMN element specified to have that attribute or property. Where a graphical representation for that attribute or property is specified as required, that graphical representation SHALL be used. Where a graphical representation for that attribute or property is specified as optional, the implementation MAY use either a graphical representation or some other mechanism. If a graphical representation is used, it SHALL be the representation specified. Where no graphical representation for that attribute or property is specified, the implementation MAY use either a graphical representation or some other
mechanism. If a graphical representation is used, it SHALL NOT conflict with the specified graphical representation of any other BPMN element.

2.1.7. Extended and Optional Elements

A conforming implementation is not required to support any element or attribute that is specified herein to be non-normative or informative. In each instance in which this specification defines a feature to be “optional,” it specifies whether the option is in:

- how the feature shall be displayed
- whether the feature shall be displayed
- whether the feature shall be supported

A conforming implementation is not required to support any feature whose support is specified to be optional. If an implementation supports an optional feature, it SHALL support it as specified. A conforming implementation SHALL support any “optional” feature for which the option is only in whether or how it shall be displayed.

2.1.8. Visual Interchange

One of the main goals of this specification is to provide an interchange format that can be used to exchange BPMN definitions (both domain model and diagram layout) between different tools. The implementation should support the metamodel for Process types specified in Section 13 to enable portability of process diagrams so that users can take business process definitions created in one vendor’s environment and use them in another vendor’s environment.

2.2. Process Execution Conformance

The next two (2) sections describe Process Execution Conformance.

2.2.1. Execution Semantics

The BPMN execution semantics have been fully formalized in this version of the specification. The tool claiming BPMN Execution Conformance type MUST fully support and interpret the operational semantics and Activity life-cycle specified in Section 14.2.2. Non-operational elements listed in Section 14 MAY be ignored by implementations claiming BPMN Execution Conformance type. Conformant implementations MUST fully support and interpret the underlying metamodel.

Note: The tool claiming Process Execution Conformance type is not expected to support and interpret Choreography models. The tool claiming Process Execution Conformance type is not expected to support Process Modeling Conformance.

2.2.2. Import of Process Diagrams

The tool claiming Process Execution Conformance type must support import of BPMN Process diagram types including its definitional Collaboration (see Table 10-1).
2.3. **BPEL Process Execution Conformance**

Special type of Process Execution Conformance that supports the BPMN mapping to WS-BPEL as specified in Section 5.1 can claim **BPEL Process Execution Conformance**.

**Note:** The tool claiming **BPEL Process Execution Conformance** must fully support Process Execution Conformance. The tool claiming **BPEL Process Execution Conformance** is not expected to support and interpret Choreography models. The tool claiming **BPEL Process Execution Conformance** is not expected to support Process Modeling Conformance.

2.4. **Choreography Modeling Conformance**

The next five (5) sections describe **Choreography Conformance**.

2.4.1. **BPMN Choreography Types**

The implementations claiming **Choreography Conformance** type must support the following BPMN packages:

- The BPMN core elements, which include those defined in the Infrastructure, Foundation, Common, and Service packages (see Chapter 1).
- Choreography diagrams, which includes the elements defined in the Choreography, and Choreography packages (see Chapter 0).
- Collaboration diagrams, which include Pools and Message Flow (see Chapter 43).

2.4.2. **BPMN Choreography elements**

The **Choreography Conformance** set includes Message, Choreography Task, Global Choreography Task, Choreography Sub-Process (expanded and collapsed), certain types of Start Events (e.g., None, Timer, Conditional, Signal, and Multiple), certain types of Intermediate Events (None, Message attached to Activity boundary, Timer – normal as well as attached to Activity boundary, Timer used in Event Gateways, Cancel attached to an Activity boundary, Conditional, Signal, Multiple, Link, etc) and certain types of End Events (None and Terminate), and Gateways. In addition, to enable Choreography within Collaboration it should support Pools and Message Flow.

2.4.3. **Visual Appearance**

An implementation that creates and displays BPMN Choreography Diagrams shall use the graphical elements, shapes and markers as specified in the BPMN specification. The use of text, color, size and lines for Choreography diagram types are listed in Section 4.4.

2.4.4. **Choreography Semantics**

The tool claiming **Choreography Conformance** should fully support and interpret the graphical and execution semantics surrounding Choreography diagram elements and Choreography diagram types.
2.4.5. Visual Interchange

The implementation should support import/export of Choreography diagram types and Collaboration diagram types that depict Choreography within collaboration as specified in Section 9.4 to enable portability of Choreography definitions, so that users can take BPMN definitions created in one vendor’s environment and use them in another vendor’s environment.

2.5. Summary of BPMN Conformance Types

Table 2-1 summarizes the requirements for BPMN Conformance.

Table 2-1 – Types of BPMN Conformance

4. Terms and Definitions

See Annex D - Glossary.

5. Symbols

There are no symbols defined in this specification.

6. Additional Information

6.1. Conventions

The section introduces the conventions used in this document. This includes (text) notational conventions and notations for schema components. Also included are designated namespace definitions.

6.2. Typographical and Linguistic Conventions and Style

This specification incorporates the following conventions:

- The keywords “MUST,” “MUST NOT,” “REQUIRED,” “SHALL,” “MUST NOT,” “SHOULD,” “SHOULD NOT,” “RECOMMENDED,” “MAY,” and “OPTIONAL” in this document are to be interpreted as described in RFC-2119.
• A **term** is a word or phrase that has a special meaning. When a term is defined, the term name is highlighted in **bold** typeface.

• A reference to another definition, section, or specification is highlighted with **underlined** typeface and provides a link to the relevant location in this specification.

• A reference to a graphical element is highlighted with a capitalized word and will be presented with the Verdana font (e.g., **Sub-Process**).

• A reference to a non-graphical element or **BPMN** construct is highlighted by being italicized and will be presented with the Times New Roman font (e.g., **Participant**).

• A reference to an attribute or model association will be presented with the Courier New font (e.g., **Expression**).

• A reference to a WSBPEL element, attribute, or construct is highlighted with an italic lower-case word, usually preceded by the word “WSBPEL” and will be presented with the Courier New font (e.g., **WSBPEL pick**).

• Non-normative examples are set off in boxes and accompanied by a brief explanation.

• XML and pseudo code is highlighted with **mono-spaced** typeface. Different font colors may be used to highlight the different components of the XML code.

• The cardinality of any content part is specified using the following operators:
  o  `<none>` — exactly once
  o  `[0..1]` — 0 or 1
  o  `[0..*]` — 0 or more
  o  `[1..*]` — 1 or more

• Attributes separated by `|` and grouped within `{` and `}` — alternative values
  o  `<value>` — default value
  o  `<type>` — the type of the attribute

### 6.3. Abbreviations

The following abbreviations may be used throughout this document:

<table>
<thead>
<tr>
<th>This abbreviation</th>
<th>Refers to</th>
</tr>
</thead>
<tbody>
<tr>
<td>WSBPEL</td>
<td>Web Services Business Process Execution Language (see WSBPEL). This abbreviation refers specifically to version 2.0 of the specification.</td>
</tr>
<tr>
<td>WSDL</td>
<td>Web Service Description Language (see WSDL). This abbreviation refers specifically to the W3C Technical Note, 15 March 2001, but is intended to support future versions of the WSDL specification</td>
</tr>
</tbody>
</table>
6.4. Structure of this Document

Section 7 discusses the scope of the specification and provides a summary of the elements introduced in subsequent sections of the document.

Section 8 introduces the BPMN Core that includes basic BPMN elements required for constructing various Business Processes, including collaborations, orchestration Processes and Choreographies.

Elements needed for modeling of Collaborations, orchestration Processes, Conversations, and Choreographies are introduced in sections 9, 10, 11 and 12, respectively.

Section 13 introduces the BPMN visual diagram model. Section 14 defines the execution semantics for Process orchestrations in BPMN 2.0. Section 15 discusses a mapping of a BPMN model to WS-BPEL that is derived by analyzing the BPMN objects and the relationships between these objects. Exchange formats and an XSLT transformation between them are provided in section 16.
7. Overview

There has been much activity in the past few years in developing web service-based XML execution languages for Business Process Management (BPM) systems. Languages such as WSBPEL provide a formal mechanism for the definition of business processes. The key element of such languages is that they are optimized for the operation and inter-operation of BPM Systems. The optimization of these languages for software operations renders them less suited for direct use by humans to design, manage, and monitor business processes. WSBPEL has both graph and block structures and utilizes the principles of formal mathematical models, such as pi-calculus. This technical underpinning provides the foundation for business process execution to handle the complex nature of both internal and B2B interactions and take advantage of the benefits of Web services. Given the nature of WSBPEL, a complex business process could be organized in a potentially complex, disjointed, and unintuitive format that is handled very well by a software system (or a computer programmer), but would be hard to understand by the business analysts and managers tasked to develop, manage, and monitor the process. Thus, there is a human level of “inter-operability” or “portability” that is not addressed by these web service-based XML execution languages.

Business people are very comfortable with visualizing Business Processes in a flow-chart format. There are thousands of business analysts studying the way companies work and defining Business Processes with simple flow charts. This creates a technical gap between the format of the initial design of Business Processes and the format of the languages, such as WSBPEL, that will execute these Business Processes. This gap needs to be bridged with a formal mechanism that maps the appropriate visualization of the Business Processes (a notation) to the appropriate execution format (a BPM execution language) for these Business Processes.

Inter-operation of Business Processes at the human level, rather than the software engine level, can be solved with standardization of the Business Process Modeling Notation (BPMN). BPMN provides a multiple diagrams, which are designed for use by the people who design and manage Business Processes. BPMN also provides a mapping to an execution language of BPM Systems (WSBPEL). Thus, BPMN would provide a standard visualization mechanism for Business Processes defined in an execution optimized business process language.

BPMN provides businesses with the capability of understanding their internal business procedures in a graphical notation and will give organizations the ability to communicate these procedures in a standard manner. Currently, there are scores of Process modeling tools and methodologies. Given that individuals will move from one company to another and that companies will merge and diverge, it is likely that business analysts are required to understand multiple representations of Business Processes—potentially different representations of the same Process as it moves through its lifecycle of development, implementation, execution, monitoring, and analysis. Therefore, a standard graphical notation will facilitate the understanding of the performance Collaborations and business transactions within and between the organizations. This will ensure that businesses will understand themselves and participants in their business and will enable organizations to adjust to new internal and B2B business circumstances quickly. BPMN follows the tradition of flowcharting notations for readability and flexibility. In addition, the BPMN execution semantics is fully formalized. The OMG is using the experience of the business process notations that have preceded BPMN to create the next generation notation that combines readability, flexibility, and expandability.

---

BPMN will also advance the capabilities of traditional business process notations by inherently handling B2B Business Process concepts, such as public and private Processes and Choreographies, as well as advanced modeling concepts, such as exception handling, transactions, and compensation.

7.1. BPMN Scope

This specification provides a notation and model for Business Processes and an interchange format that can be used to exchange BPMN Process definitions (both domain model and diagram layout) between different tools. The goal of the specification is to enable portability of Process definitions, so that users can take Process definitions created in one vendor’s environment and use them in another vendor’s environment.

The BPMN 2.0 specification extends the scope and capabilities of the BPMN 1.2 in several areas:

- Formalizes the execution semantics for all BPMN elements
- Defines an extensibility mechanism for both Process model extensions and graphical extensions
- Refines Event composition and correlation
- Extends the definition of human interactions
- Defines a Choreography model

This specification also resolves known BPMN 1.2 inconsistencies and ambiguities.

BPMN is constrained to support only the concepts of modeling that are applicable to Business Processes. This means that other types of modeling done by organizations for business purposes is out of scope for BPMN. Therefore, the following are aspects that are out of the scope of this specification:

- Definition of organizational models and resources
- Modeling of functional breakdowns
- Data and information models
- Modeling of strategy
- Business rules models

Since these types of high-level modeling either directly or indirectly affect Business Processes, the relationships between BPMN and other high-level business modeling can be defined more formally as BPMN and other specifications are advanced.

While BPMN shows the flow of data (Messages), and the association of data artifacts to Activities, it is not a data flow language. In addition, operational simulation, monitoring and deployment of Business Processes are out of scope of this specification.

BPMN 2.0 may be mapped to more than one platform dependent process modeling language, e.g. WS-BPEL 2.0. This document includes a mapping of a subset of BPMN to WS-BPEL 2.0. Mappings to other emerging standards are considered to be separate efforts.

The specification utilizes other standards for defining data types, expressions and service operations. These standards are XML Schema, XPath, and WSDL, respectively.
7.1.1. Uses of BPMN

Business Process modeling is used to communicate a wide variety of information to a wide variety of audiences. BPMN is designed to cover many types of modeling and allows the creation of end-to-end Business Processes. The structural elements of BPMN allow the viewer to be able to easily differentiate between sections of a BPMN Diagram. There are three basic types of sub-models within an end-to-end BPMN model:

- Processes (Orchestration), including:
  - Private Non-executable (internal) Business Processes
  - Private Executable (internal) Business Processes
  - Public Processes
- Choreographies
- Collaborations, which may include Processes and/or Choreographies
  - A view of Conversations

Private (Internal) Business Processes

Private Business Processes are those internal to a specific organization. These Processes have been generally called workflow or BPM Processes (see Figure 10-4). Another synonym typically used in the Web services area is the Orchestration of services. There are two (2) types of private Processes: executable and non-executable. An executable Process is a Process that has been modeled for the purpose of being executed according to the semantics defined in Chapter 14 (see page 426). Of course, during the development cycle of the Process, there will be stages where the Process does not have enough detail to be “executable.” A non-executable Process is a private Process that has been modeled for the purpose of documenting Process behavior at a modeler-defined level of detail. Thus, information required for execution, such as formal condition expressions are typically not included in a non-executable Process.

If a swimlanes-like notation is used (e.g., a Collaboration, see below) then a private Business Process will be contained within a single Pool. The Process flow is therefore contained within the Pool and cannot cross the boundaries of the Pool. The flow of Messages can cross the Pool boundary to show the interactions that exist between separate private Business Processes.

![Diagram of a private Business Process]

Figure 7-1 – Example of a private Business Process

Public Processes

A public Process represents the interactions between a private Business Process and another Process or Participant (see Figure 10-5). Only those Activities that are used to communicate to the other Participant(s) are included in the public Process. All other “internal” Activities of the private Business Process are not shown in the public Process. Thus, the public Process shows to the outside world the Message Flow and the order of those Message Flow that are required to interact with that Process. Public Processes can be
modeled separately or within a **Collaboration** to show the flow of **Messages** between the **public** **Process Activities** and other **Participants**. Note that the **public** **type** of **Process** was named “abstract” in BPMN 1.2.

**Figure 7-2 – Example of a public Process**

**Collaborations**

A **Collaboration** depicts the interactions between two or more business entities. A **Collaboration** contains two (2) or more **Pools**, representing the **Participants** in the **Collaboration**. The **Message** exchange between the **Participants** is shown by a **Message Flow** that connects two (2) **Pools** (or the objects within the **Pools**). The **Messages** associated with the **Message Flow** may also be shown. The **Collaboration** can be shown as two or more **public Processes** communicating with each other (see **Figure 7-3**). With a **public Process**, the **Activities** for the **Collaboration** participants can be considered the “touch-points” between the participants. The corresponding internal (executable) **Processes** are likely to have much more **Activity** and detail than what is shown in the **public Processes**. Or a **Pool** may be empty, a “black box.” **Choreographies** may be shown “in between” the **Pools** as they bisect the **Message Flow** between the **Pools**. All combinations of **Pools**, **Processes**, and a **Choreography** are allowed in a **Collaboration**.
Choreographies

A self-contained Choreography (no Pools or Orchestration) is a definition of the expected behavior, basically a procedural contract, between interacting Participants. While a normal Process exists within a Pool, a Choreography exists between Pools (or Participants).

The Choreography looks similar to a private Business Process since it consists of a network of Activities, Events, and Gateways (see Figure 7-4). However, a Choreography is different in that the Activities are interactions that represent a set (1 or more) of Message exchanges, which involves two (2) or more Participants. In addition, unlike a normal Process, there is no central controller, responsible entity or observer of the Process.

Conversations

The Conversation diagram is similar to a Collaboration diagram. However, the Pools of a Conversation are not allowed to contain a Process and a Choreography is not allowed to be placed in between the Pools of a Conversation diagram. A Conversation is the logical relation of Message.
Message exchanges are related to each other and reflect distinct business scenarios. For example, in logistics, stock replenishments involve the following types scenarios: creation of sales orders; assignment of carriers for shipments combining different sales orders; crossing customs/quarantine; processing payment and investigating exceptions. Thus, a Conversation diagram, as shown in Figure 7-5, shows Communications (as hexagons) between Participants (Pools). This provides a “bird’s eye” perspective of the different Conversations which relate to the domain.

Figure 7-5 – An example of a Conversation diagram

Diagram Point of View

Since a BPMN Diagram may depict the Processes of different Participants, each Participant may view the Diagram differently. That is, the Participants have different points of view regarding how the Processes will apply to them. Some of the Activities will be internal to the Participant (meaning performed by or under control exchanges. The logical relation, in practice, often concerns a business object(s) of interest, e.g. “Order,” “Shipment and Delivery,” or “Invoice.”
of the Participant) and other Activities will be external to the Participant. Each Participant will have a different perspective as to which are internal and external. At runtime, the difference between internal and external Activities is important in how a Participant can view the status of the Activities or troubleshoot any problems. However, the Diagram itself remains the same. Figure 7-3, above, displays a Business Process that has two points of view. One point of view is of a Patient, the other is of the Doctor’s office. The Diagram shows the Activities of both participants in the Process, but when the Process is actually being performed, each Participant will only have control over their own Activities. Although the Diagram point of view is important for a viewer of the Diagram to understand how the behavior of the Process will relate to that viewer, BPMN will not currently specify any graphical mechanisms to highlight the point of view. It is open to the modeler or modeling tool vendor to provide any visual cues to emphasize this characteristic of a Diagram.

Understanding the Behavior of Diagrams

Throughout this document, we discuss how Sequence Flow is used within a Process. To facilitate this discussion, we employ the concept of a token that will traverse the Sequence Flow and pass through the elements in the Process. A token is a theoretical concept that is used as an aid to define the behavior of a Process that is being performed. The behavior of Process elements can be defined by describing how they interact with a token as it “traverses” the structure of the Process. However, modeling and execution tools that implement BPMN are not required to implement any form of token.

A Start Event generates a token that must eventually be consumed at an End Event (which may be implicit if not graphically displayed). The path of tokens should be traceable through the network of Sequence Flow, Gateways, and Activities within a Process.

Note: A token does not traverse the Message Flow since it is a Message that is passed down a Message Flow (as the name implies).

7.2. BPMN Elements

It should be emphasized that one of the drivers for the development of BPMN is to create a simple and understandable mechanism for creating Business Process models, while at the same time being able to handle the complexity inherent to Business Processes. The approach taken to handle these two conflicting requirements was to organize the graphical aspects of the notation into specific categories. This provides a small set of notation categories so that the reader of a BPMN diagram can easily recognize the basic types of elements and understand the diagram. Within the basic categories of elements, additional variation and information can be added to support the requirements for complexity without dramatically changing the basic look and feel of the diagram. The five (5) basic categories of elements are:

- Flow Objects
- Data
- Connecting Objects
- Swimlanes
- Artifacts

Flow Objects are the main graphical elements to define the behavior of a Business Process. There are three (3) Flow Objects:
• Events
• Activities
• Gateways

*Data* is represented with the five (5) elements:

• Data Objects
• Data Inputs
• Data Outputs
• Data Stores
• Properties

There are four (4) ways of connecting the Flow Objects to each other or other information. There are four (4) Connecting Objects:

• Sequence Flow
• Message Flow
• Association
• Data Association

There are two (2) ways of grouping the primary modeling elements through “Swimlanes:”

• Pools
• Lanes

*Artifacts* are used to provide additional information about the *Process*. There are two (2) standardized *Artifacts*, but modelers or modeling tools are free to add as many *Artifacts* as required. There may be additional BPMN efforts to standardize a larger set of *Artifacts* for general use or for vertical markets. The current set of *Artifacts* includes:

• Group
• Text Annotation
### 7.2.1. Basic BPMN Modeling Elements

Table 7-1 displays a list of the basic modeling elements that are depicted by the notation.

**Table 7-1 - Basic Modeling Elements**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event</td>
<td>An Event is something that “happens” during the course of a Process (see page 239) or a Choreography (see page 369). These Events affect the flow of the model and usually have a cause (trigger) or an impact (result). Events are circles with open centers to allow internal markers to differentiate different triggers or results. There are three types of Events, based on when they affect the flow: Start, Intermediate, and End.</td>
<td><img src="image" alt="Event" /></td>
</tr>
<tr>
<td>Activity</td>
<td>An Activity is a generic term for work that company performs (see page 159) in Process. An Activity can be atomic or non-atomic (compound). The types of Activities that are a part of a Process Model are: Sub-Process and Task, which are rounded rectangles. Activities are used in both standard Processes and in Choreographies.</td>
<td><img src="image" alt="Activity" /></td>
</tr>
<tr>
<td>Gateway</td>
<td>A Gateway is used to control the divergence and convergence of Sequence Flow in a Process (see page 295) and in a Choreography (see page 375). Thus, it will determine branching, forking, merging, and joining of paths. Internal markers will indicate the type of behavior control.</td>
<td><img src="image" alt="Gateway" /></td>
</tr>
<tr>
<td>Sequence Flow</td>
<td>A Sequence Flow is used to show the order that Activities will be performed in a Process (see page 125) and in a Choreography (see page 348).</td>
<td><img src="image" alt="Sequence Flow" /></td>
</tr>
<tr>
<td><strong>Message Flow</strong></td>
<td>A Message Flow is used to show the flow of Messages between two <em>Participants</em> that are prepared to send and receive them (see page 119). In BPMN, two separate Pools in a Collaboration Diagram will represent the two Participants (e.g., PartnerEntities and/or PartnerRoles).</td>
<td></td>
</tr>
<tr>
<td><strong>Association</strong></td>
<td>An Association is used to link information and Artifacts with BPMN graphical elements (see page 88). Text Annotations (see page 93) and other Artifacts (see page 86) can be Associated with the graphical elements. An arrowhead on the Association indicates a direction of flow (e.g., data), when appropriate.</td>
<td></td>
</tr>
<tr>
<td><strong>Pool</strong></td>
<td>A Pool is the graphical representation of a <em>Participant</em> in a Collaboration (see page 146). It is also acts as a “swimlane” and a graphical container for partitioning a set of Activities from other Pools, usually in the context of B2B situations.</td>
<td></td>
</tr>
<tr>
<td><strong>Lane</strong></td>
<td>A Lane is a sub-partition within a Process, sometimes within a Pool, and will extend the entire length of the Process, either vertically or horizontally (see on page 149). Lanes are used to organize and categorize Activities.</td>
<td></td>
</tr>
<tr>
<td><strong>Data Object</strong></td>
<td>Data Objects provide information about what Activities require to be performed and/or what they produce (see page 213). Data Objects can represent a singular object or a collection of objects. Data Input and Data Output provide the same information for Processes.</td>
<td></td>
</tr>
<tr>
<td><strong>Message</strong></td>
<td>A Message is used to depict the contents of a communication between two <em>Participants</em> (as defined by a business PartnerRole or a business PartnerEntity—see on page 112).</td>
<td></td>
</tr>
<tr>
<td>Group (a box around a group of objects within the same category)</td>
<td>A Group is a grouping of Activities that are within the same Category (see page 89). This type of grouping does not affect the Sequence Flow of the Activities within the Group. The Category name appears on the diagram as the group label. Categories can be used for documentation or analysis purposes. Groups are one way in which Categories of objects can be visually displayed on the diagram.</td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td></td>
</tr>
<tr>
<td>Text Annotation (attached with an Association)</td>
<td>Text Annotations are a mechanism for a modeler to provide additional text information for the reader of a BPMN Diagram (see page 92).</td>
<td>Descriptive Text Here</td>
</tr>
</tbody>
</table>
### 7.2.2. Extended BPMN Modeling Elements

Table 7-2 displays a more extensive list of the Business Process concepts that could be depicted through a business process modeling notation.

**Table 7-2 – BPMN Extended Modeling Elements**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event</td>
<td>An Event is something that “happens” during the course of a Process (see page 239) or a Choreography (see page 369). These Events affect the flow of the model and usually have a cause (Trigger) or an impact (Result). Events are circles with open centers to allow internal markers to differentiate different Triggers or Results. There are three types of Events, based on when they affect the flow: Start, Intermediate, and End.</td>
<td></td>
</tr>
<tr>
<td>Flow Dimension (e.g., Start, Intermediate, End)</td>
<td>Start Event indicates where a particular Process (see page 244) or Choreography (see page 369) will start.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Intermediate Events occur between a Start Event and an End Event. They will affect the flow of the Process (see page 256) or Choreography (see page 371), but will not start or (directly) terminate the Process.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>End Event indicates where a Process (see page 252) or Choreography (see page 374) will end.</td>
<td></td>
</tr>
</tbody>
</table>
Type Dimension (e.g., None, Message, Timer, Error, Cancel, Compensation, Conditional, Link, Signal, Multiple, Terminate.)

The Start and some Intermediate Events have “triggers” that define the cause for the Event (see [Start Event] on page 244 and [Intermediate Event] on page 256). There are multiple ways that these events can be triggered. End Events may define a “result” that is a consequence of a Sequence Flow ending (see page 252). Start Events can only react to (“catch”) a trigger. End Events can only create (“throw”) a result. Intermediate Events can catch or throw triggers. For the Events, triggers that catch, the markers are unfilled, and for triggers and results that throw, the markers are filled.

Additionally, some Events, which were used to interrupt Activities in BPMN 1.1, can now be used in a mode that is does not interrupt. The boundary of these Event is dashed (see page 268).

Activity
An Activity is a generic term for work that company performs (see page 159) in Process. An Activity can be atomic or non-atomic (compound). The types of Activities that are a part of a Process Model are: Sub-Process and Task, which are rounded rectangles. Activities are used in both standard Processes and in Choreographies.

Task (Atomic)
A Task is an atomic Activity that is included within a Process (see page 162). A Task is used when the work in the Process is not broken down to a finer level of Process detail.
<p>| Choreography Task | A Choreography Task is an atomic Activity in a Choreography (see page 350). It represents a set of one (1) or more Message exchanges. Each Choreography Task involves two (2) or more Participants. The name of the Choreography Task and each of the Participants are all displayed in the different bands that make up the shape’s graphical notation. There are two (2) more Participant Bands and one Task Name Band. |
| Process/Sub-Process (non-atomic) | A Sub-Process is a compound Activity that is included within a Process (see page 176) or Choreography (see page 356). It is compound in that it can be broken down into a finer level of detail (a Process or Choreography) through a set of sub-Activities. |
| Collapsed Sub-Process | The details of the Sub-Process are not visible in the Diagram (see page 176). A “plus” sign in the lower-center of the shape indicates that the Activity is a Sub-Process and has a lower-level of detail. |
| Expanded Sub-Process | The boundary of the Sub-Process is expanded and the details (a Process) are visible within its boundary (see page 176). Note that Sequence Flow cannot cross the boundary of a Sub-Process. |
| Collapsed Choreography Sub-Process | The details of the Choreography Sub-Process are not visible in the Diagram (see page 356). A “plus” sign in the lower-center of the Task Name Band of the shape indicates that the Activity is a Sub-Process and has a lower-level of detail. |</p>
<table>
<thead>
<tr>
<th>Expanded Choreography Sub-Process</th>
<th>The boundary of the Choreography Sub-Process is expanded and the details (a Choreography) are visible within its boundary (see page 356). Note that Sequence Flow cannot cross the boundary of a Choreography Sub-Process.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gateway</td>
<td>A Gateway is used to control the divergence and convergence of Sequence Flow in a Process (see page 295) and in a Choreography (see page 375). Thus, it will determine branching, forking, merging, and joining of paths. Internal markers will indicate the type of behavior control (see below).</td>
</tr>
</tbody>
</table>
| Gateway Control Types            | Icons within the diamond shape of the Gateway will indicate the type of flow control behavior. The types of control include:  
  - Exclusive decision and merging. Both Exclusive (see page 298) and Event-Based (see page 307). Exclusive can be shown with or without the “X” marker.  
  - Inclusive Gateway decision and merging (see page 300)  
  - Complex Gateway -- complex conditions and situations (e.g., 3 out of 5; page 304)  
  - Parallel Gateway forking and joining (see page 302)  
  Each type of control affects both the incoming and outgoing flow. |
<p>| Sequence Flow                    | A Sequence Flow is used to show the order that Activities will be performed in a Process (see page 159) and in a Choreography (see page 348). See next seven figures |</p>
<table>
<thead>
<tr>
<th>Normal Flow</th>
<th>Normal flow refers to the series of Sequence Flow that originates from a Start Event and continues through activities via alternative and parallel paths until it ends at an End Event. This does not include the paths that start from an Intermediate Event attached to the boundary of an Activity.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uncontrolled flow</td>
<td>Uncontrolled flow refers to flow that is not affected by any conditions or does not pass through a Gateway. The simplest example of this is a single Sequence Flow connecting two Activities. This can also apply to multiple Sequence Flow that converge to or diverge from an Activity. For each uncontrolled Sequence Flow a token will flow from the source object through the Sequence Flow to the target object.</td>
</tr>
<tr>
<td>Conditional flow</td>
<td>Sequence Flow can have condition Expressions that are evaluated at runtime to determine whether or not the Sequence Flow will be used (i.e., will a token travel down the Sequence Flow – see page 109). If the conditional flow is outgoing from an Activity, then the Sequence Flow will have a mini-diamond at the beginning of the connector (see figure to the right). If the conditional flow is outgoing from a Gateway, then the line will not have a mini-diamond (see figure in the row above).</td>
</tr>
<tr>
<td>Default flow</td>
<td>For Data-Based Exclusive Gateways or Inclusive Gateways, one type of flow is the Default condition flow (see page 109). This flow will be used only if all the other outgoing conditional flow is not true at runtime. These Sequence Flow will have a diagonal slash will be added to the beginning of the connector (see the figure to the right).</td>
</tr>
<tr>
<td>Exception Flow</td>
<td><em>Exception flow occurs outside the normal flow of the Process and is based upon an Intermediate Event attached to the boundary of an Activity that occurs during the performance of the Process (see page 285).</em></td>
</tr>
<tr>
<td>Message Flow</td>
<td>A Message Flow is used to show the flow of Messages between two Participants that are prepared to send and receive them (see page 119). In BPMN, two separate Pools in a Collaboration Diagram will represent the two Participants (e.g., PartnerEntities and/or PartnerRoles).</td>
</tr>
<tr>
<td>Compensation Association</td>
<td><em>Compensation Association occurs outside the normal flow of the Process and is based upon a Compensation Intermediate Event that is triggered through the failure of a transaction or a throw Compensate Event (see page 270).</em> The target of the Association must be marked as a Compensation Activity.</td>
</tr>
<tr>
<td>Data Object</td>
<td>Data Objects provide information about what Activities require to be performed and/or what they produce (see page 213). Data Objects can represent a singular object or a collection of objects. Data Input and Data Output provide the same information for Processes.</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Message</td>
<td>A Message is used to depict the contents of a communication between two Participants (as defined by a business PartnerRole or a business PartnerEntity—see on page 112).</td>
</tr>
</tbody>
</table>
| Fork | BPMN uses the term “fork” to refer to the dividing of a path into two or more parallel paths (also known as an AND-Split). It is a place in the Process where activities can be performed concurrently, rather than sequentially.

There are two options:

Multiple Outgoing Sequence Flow can be used (see figure top-right). This represents “uncontrolled” flow is the preferred method for most situations.

A Parallel Gateway can be used (see figure bottom-right). This will be used rarely, usually in combination with other Gateways. |

| Join | BPMN uses the term “join” to refer to the combining of two or more parallel paths into one path (also known as an AND-Join or synchronization).

A Parallel Gateway is used to show the joining of multiple Sequence Flow. |

| Decision, Branching Point | Decisions are Gateways within a Process (see page 295) or a Choreography (see page 375) where the flow of control can take one or more alternative paths. See next five rows. |

<p>| Exclusive | This Decision represents a branching point where Alternatives are based on conditional expressions contained within the outgoing Sequence Flow (see page 298 or page 375). Only one of the Alternatives will be chosen. |</p>
<table>
<thead>
<tr>
<th>Decision Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event-Based</td>
<td>This Decision represents a branching point where Alternatives are based on an Event that occurs at that point in the Process (see page 307) or Choreography (see page 375). The specific Event, usually the receipt of a Message, determines which of the paths will be taken. Other types of Events can be used, such as Timer. Only one of the Alternatives will be chosen. There are two options for receiving Messages: Tasks of Type Receive can be used (see figure top-right). Intermediate Events of Type Message can be used (see figure bottom-right).</td>
</tr>
<tr>
<td>Inclusive</td>
<td>This Decision represents a branching point where Alternatives are based on conditional expressions contained within the outgoing Sequence Flow (see page 300). In some sense it is a grouping of related independent Binary (Yes/No) Decisions. Since each path is independent, all combinations of the paths may be taken, from zero to all. However, it should be designed so that at least one path is taken. A Default Condition could be used to ensure that at least one path is taken. There are two versions of this type of Decision: The first uses a collection of conditional Sequence Flow, marked with mini-diamonds (see top-right figure). The second uses an Inclusive Gateway (see bottom-right picture).</td>
</tr>
</tbody>
</table>
| Merging | BPMN uses the term “merge” to refer to the exclusive combining of two or more paths into one path (also known as an OR-Join).  
A Merging Exclusive Gateway is used to show the merging of multiple Sequence Flow.  
If all the incoming flow is alternative, then a Gateway is not needed. That is, uncontrolled flow provides the same behavior. |

7.3. BPMN Diagram Types

The BPMN 2.0 aims to cover three basic models of Processes: private Processes (both executable and non-executable), public Processes, and Choreographies. Within and between these three BPMN sub-models, many types of Diagrams can be created. The following are examples of Business Processes that can be modeled using BPMN 2.0:

- High-level non-executable Process Activities (not functional breakdown)
- Detailed executable Business Process
- As-is or old Business Process
- To-be or new Business Process
- A description of expected behavior between two (2) or more business Participants—a Choreography.
- Detailed private Business Process (either executable or non-executable) with interactions to one or more external Entities (or “Black Box” Processes)
- Two or more detailed executable Processes interacting
- Detailed executable Business Process relationship to a Choreography
- Two or more public Processes
- Public Process relationship to Choreography
- Two or more detailed executable Business Processes interacting through a Choreography

BPMN is designed to allow describing all above examples of Business Processes. However, the ways that different sub-models are combined is left to tool vendors. A BPMN 2.0 compliant implementation may recommend that modelers pick a focused purpose, such as a private Process, or Choreographies. However, the BPMN 2.0 specification makes no assumptions.

7.4. Use of Text, Color, Size, and Lines in a Diagram

Text Annotation objects can be used by the modeler to display additional information about a Process or attributes of the objects within a BPMN Diagram.

- Flow objects and Flow MAY have labels (e.g., its name and/or other attributes) placed inside the shape, or above or below the shape, in any direction or location, depending on the preference of the modeler or modeling tool vendor.
- The fills that are used for the graphical elements MAY be white or clear.
- The notation MAY be extended to use other fill colors to suit the purpose of the modeler or tool (e.g., to highlight the value of an object attribute). However,
  - The markers for “throwing” Events MUST have a dark fill (see “End Event” on page 252 and “Intermediate Event” on page 256 for more details).
  - Participant Bands for Choreography Tasks and Choreography Sub-Processes that are not the initiator of the Activity MUST have a light fill (see “Choreography Task”
Flow objects and markers MAY be of any size that suits the purposes of the modeler or modeling tool.

- The lines that are used to draw the graphical elements MAY be black.
- The notation MAY be extended to use other line colors to suit the purpose of the modeler or tool (e.g., to highlight the value of an object attribute).
- The notation MAY be extended to use other line styles to suit the purpose of the modeler or tool (e.g., to highlight the value of an object attribute) with the condition that the line style MUST NOT conflict with any current BPMN defined line style. Thus, the line styles of Sequence Flow, Message Flow, and Text Associations MUST NOT be modified or duplicated.

7.5. Flow Object Connection Rules

An incoming Sequence Flow can connect to any location on a Flow Object (left, right, top, or bottom). Likewise, an outgoing Sequence Flow can connect from any location on a Flow Object (left, right, top, or bottom). A Message Flow also has this capability. BPMN allows this flexibility; however, we also recommend that modelers use judgment or best practices in how Flow Objects should be connected so that readers of the Diagrams will find the behavior clear and easy to follow. This is even more important when a Diagram contains Sequence Flow and Message Flow. In these situations it is best to pick a direction of Sequence Flow, either left to right or top to bottom, and then direct the Message Flow at a 90° angle to the Sequence Flow. The resulting Diagrams will be much easier to understand.

7.5.1. Sequence Flow Connections Rules

Table 8.4 displays the BPMN Flow Objects and shows how these objects can connect to one another through Sequence Flow. These rules apply to the connections within a Process Diagram and within a Choreography Diagram. The \( \rightarrow \) symbol indicates that the object listed in the row can connect to the object listed in the column. The quantity of connections into and out of an object is subject to various configuration dependencies are not specified here. Refer to the sections in the next chapter for each individual object for more detailed information on the appropriate connection rules. Note that if a Sub-Process has been expanded within a Diagram, the objects within the Sub-Process cannot be connected to objects outside of the Sub-Process. Nor can Sequence Flow cross a Pool boundary.

</table>

**Note** – Only those objects that can have incoming and/or outgoing Sequence Flow are shown in the table. Thus, Pool, Lane, Data Object, Group, and Text Annotation are not listed in the table. Also, the Activity shapes in the table represent Activities and Sub-Processes for Processes, and Choreography Activities and Choreography Sub-Processes for Choreography.

### 7.5.2. Message Flow Connection Rules

Table 8.5 displays the BPMN modeling objects and shows how these objects can connect to one another through Message Flow. These rules apply to the connections within a Collaboration Diagram. The ➔ symbol indicates that the object listed in the row can connect to the object listed in the column. The quantity of connections into and out of an object is subject to various configuration dependencies are not specified here. Refer to the sections in the next chapter for each individual object for more detailed information on the appropriate connection rules. **Note that Message Flow cannot connect to objects that are within the same Pool.**
Table 7-4 – Message Flow Connection Rules

<table>

</table>

Note – Only those objects that can have incoming and/or outgoing Message Flow are shown in the table. Thus, Lane, Gateway, Data Object, Group, and Text Annotation are not listed in the table.

7.6. BPMN Extensibility

BPMN 2.0 introduces an extensibility mechanism that allows extending standard BPMN elements with additional attributes. It can be used by modelers and modeling tools to add non-standard elements or Artifacts to satisfy a specific need, such as the unique requirements of a vertical domain, and still have valid BPMN Core. Extension attributes must not contradict the semantics of any BPMN element. In addition, while extensible, BPMN Diagrams should still have the basic look-and-feel so that a Diagram by any modeler should be easily understood by any viewer of the Diagram. Thus the footprint of the basic flow elements (Events, Activities, and Gateways) must not be altered.

The specification differentiates between mandatory and optional extensions (Section § 8.2.3 explains the syntax used to declare extensions). If a mandatory extension is used, a compliant implementation must understand the extension. If an optional extension is used, a compliant implementation may ignore the extension.

7.7. BPMN Example

The following is an example of a manufacturing process from different perspectives.
Figure 7-6 – An example of a Collaboration diagram with black-box Pools
Figure 7-7 – An example of a stand-alone Choreography diagram
Figure 7-8 – An example of a stand-alone Process (Orchestration) diagram
8. BPMN Core Structure

**Note:** The content of this chapter is required for all BPMN conformance types. For more information about BPMN conformance types, see page 28.

The proposed technical structuring of BPMN is based on the concept of extensibility layers on top of a basic series of simple elements identified as *Core Elements* of the specification. From this core set of constructs, layering is used to describe additional elements of the specification that extend and add new constructs to the specification and relies on clear dependency paths for resolution. The XML Schema model lends itself particularly well to the proposed structuring model with formalized import and resolution mechanics that remove ambiguities in the definitions of elements in the outer layers of the specification.

![BPMN Core and Layer Structure](image)

**Figure 8-1 – A representation of the BPMN Core and Layer Structure**

Figure 8-1 shows the basic principles of layering that can be composed in well defined ways. The approach uses formalization constructs for extensibility that are applied consistently to the definition.

The additional effect of layering is that compatibility layers can be built, allowing for different levels of compliance amongst vendors, and also enabling vendors to add their own layers in support of different vertical industries or target audiences. In addition, it provides mechanism for the redefinition of previously existing concepts without affecting backwards compatibility, but defining two or more non-composable layers, the level of compliance with the specification and backwards compatibility can be achieved without compromising clarity.
The BPMN specification is structured in layers, where each layer builds on top of and extends lower layers. Included is a Core or kernel which includes the most fundamental elements of BPMN that are required for constructing BPMN diagrams: Process, Choreography, Collaboration, and Conversation. The Core is intended to be simple, concise, and extendable, with well defined behavior.

The Core contains three (3) sub-packages (see Figure 8-2):

- **Foundation**: The fundamental constructs needed for BPMN semantic modeling.
- **Service**: The fundamental constructs needed for modeling services and interfaces.
- **Common**: Those classes which are common to the layers of Process, Choreography, and Collaboration.

Figure 8-2 – Class diagram showing the core packages
Figure 8-3 displays the organization of the main set of BPMN core model elements.

Figure 8-3 – Class diagram showing the organization of the core BPMN elements

8.1. Infrastructure

The BPMN Infrastructure package contains two (2) elements that are used for both semantic models and diagram models.

8.1.1. Definitions

The Definitions class is the outermost containing object for all BPMN elements. It defines the scope of visibility and the namespace for all contained elements. The interchange of BPMN files will always be through one or more Definitions.
The Definitions element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-1 presents the additional attributes and model associations of the Definitions element:

Table 8-1 – Definitions attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetNamespace: string</td>
<td>This attribute identifies the namespace associated with the Definition and follows the convention established by XML Schema.</td>
</tr>
<tr>
<td>expressionLanguage: string [0..1]</td>
<td>This attribute identifies the formal expression language used in Expressions within the elements of this Definition. The Default is “<a href="http://www.w3.org/1999/XPath%E2%80%9D">http://www.w3.org/1999/XPath”</a>. This value may be overridden on each individual formal expression.</td>
</tr>
</tbody>
</table>
**typeLanguage**: string [0..1]  
This attribute identifies the type system used by the elements of this Definition. Defaults to [http://www.w3.org/2001/XMLSchema](http://www.w3.org/2001/XMLSchema). This value can be overridden on each individual ItemDefinition.

**rootElements**: RootElement [0..*]  
This attribute lists the root elements that are at the root of this Definitions. These elements can be referenced within this Definitions and are visible to other Definitions.

**diagrams**: Diagram [0..*]  
This attribute lists the Diagrams that are contained within this Definitions (see page 398 for more information on Diagrams).

**imports**: Import [0..*]  
This attribute is used to import externally defined elements and make them available for use by elements within this Definitions.

**extensions**: Extension [0..*]  
This attribute identifies extensions beyond the attributes and model associations in the base BPMN specification. See page 77 for additional information on extensibility.

**relationships**: Relationship [0..*]  
This attribute enables the extension and integration of BPMN models into larger system/development Processes.

### 8.1.2. Import

The **Import** class is used when referencing external element, either BPMN elements contained in other BPMN Definitions or non-BPMN elements. Imports must be explicitly defined.

Table 8-2 presents the attributes of **Import**:  

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>importType: string</td>
<td>Specifies the style of import associated with the element. For example, a value of “<a href="http://www.w3.org/2001/XMLSchema%E2%80%9D">http://www.w3.org/2001/XMLSchema”</a> indicates that the imported element is an XML schema. A value of <a href="http://www.omg.org/bpmn20">http://www.omg.org/bpmn20</a> indicates that the imported element is a BPMN element.</td>
</tr>
<tr>
<td>location: string [0..1]</td>
<td>Identifies the location of the imported element.</td>
</tr>
<tr>
<td>namespace: string</td>
<td>Identifies the namespace of the imported element.</td>
</tr>
</tbody>
</table>
8.1.3. Infrastructure Package XML Schemas

Table 8-3 – Definitions XML schema

  <xsd:attribute name="expressionLanguage" type="xsd:anyURI" use="optional" default="http://www.w3.org/1999/XPath"/>
  <xsd:attribute name="typeLanguage" type="xsd:anyURI" use="optional" default="http://www.w3.org/2001/XMLSchema"/>
  <xsd:anyAttribute namespace="##other" processContents="lax"/>
</xsd:complexType>
```

Table 8-4 – Import XML schema

```xml
<xsd:element name="import" type="tImport"/>
<xsd:complexType name="tImport">
  <xsd:attribute name="namespace" type="xsd:anyURI" use="required"/>
  <xsd:attribute name="location" type="xsd:string" use="required"/>
  <xsd:attribute name="importType" type="xsd:anyURI" use="required"/>
</xsd:complexType>
```

8.2. Foundation

The Foundation package contains classes which are shared amongst other packages in the Core (see Figure 8-5) of a semantic model.
8.2.1. Base Element

`BaseElement` is the abstract super class for most `BPMN` elements. It provides the attributes `id` and `documentation`, which other elements will inherit.
Table 8-5 presents the attributes and model associations for the BaseElement.

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>id: string</td>
<td>This attribute is used to uniquely identify BPMN elements.</td>
</tr>
<tr>
<td>documentation:</td>
<td>This attribute is used to annotate the BPMN element, such as descriptions and other documentation.</td>
</tr>
<tr>
<td>extensionDefinitions:</td>
<td>This attribute is used to attach additional attributes and associations to any BaseElement. This association is not applicable when the XML schema interchange is used, since the XSD mechanisms for supporting anyAttribute and any element already satisfy this requirement. See page 77 for additional information on extensibility.</td>
</tr>
<tr>
<td>extensionValues:</td>
<td>This attribute is used to provide values for extended attributes and model associations. This association is not applicable when the XML schema interchange is used, since the XSD mechanisms for supporting anyAttribute and any element already satisfy this requirement. See page 77 for additional information on extensibility.</td>
</tr>
</tbody>
</table>

8.2.2. Documentation

All BPMN elements that inherit from the BaseElement will have the capability, through the Documentation element, to have one (1) or more text descriptions of that element.

The Documentation element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-6 presents the additional attributes of the Documentation element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>text: string</td>
<td>This attribute is used to capture the text descriptions of a BPMN element.</td>
</tr>
</tbody>
</table>

8.2.3. Extensibility

The BPMN metamodel is aimed to be extensible. This allows BPMN adopters to extend the specified metamodel in a way that allows them to be still BPMN-compliant.

It provides a set of extension elements, which allows BPMN adopters to attach additional attributes and elements to standard and existing BPMN elements.
This approach results in more interchangeable models, because the standard elements are still intact and can still be understood by other BPMN adopters. It’s only the additional attributes and elements that may be lost during interchange.

A BPMN Extension basically consists of four different elements:

- Extension
- ExtensionDefinition
- ExtensionAttributeDefinition
- ExtensionAttributeValue

The core elements of an Extension are the ExtensionDefinition and ExtensionAttributeDefinition. The latter defines a list of attributes which can be attached to any BPMN element. The attribute list defines the name and type of the new attribute. This allows BPMN adopters to integrate any meta model into the BPMN meta model and reuse already existing model elements.

The ExtensionDefinition itself can be created independent of any BPMN element or any BPMN definition.

In order to use an ExtensionDefinition within a BPMN model definition (Definitions element), the ExtensionDefinition must be associated with an Extension element which binds the

---

Figure 8-6 – Extension class diagram
Proposal for:

**79 Business Process Model and Notation (BPMN), v2.0**

**ExtensionDefinition** to a specific BPMN model definition. The Extension element itself is contained within the BPMN element Definitions and therefore available to be associated with any BPMN element making use of the ExtensionDefinition.

Every BPMN element which subclasses the BPMN BaseElement can be extended by additional attributes. This works by associating a BPMN element with an ExtensionDefinition which was defined at the BPMN model definitions level (element Definitions).

Additionally, every “extended” BPMN element contains the actual extension attribute value. The attribute value, defined by the element ExtensionAttributeValue contains the value of type Element. It also has an association to the corresponding attribute definition.

**Extension**

The Extension element binds/imports an ExtensionDefinition and its attributes to a BPMN model definition.

Table 8-7 presents the attributes and model associations for the Extension element:

**Table 8-7 – Extension attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>mustUnderstand</td>
<td>boolean [0..1] = False This flag defines if the semantics defined by the extension definition and its attribute definition must be understood by the BPMN adopter in order to process the BPMN model correctly. Defaults to False.</td>
</tr>
<tr>
<td>definition:</td>
<td>ExtensionDefinition Defines the content of the extension. Note that in the XML schema, this definition is provided by an external XML schema file and is simply referenced by QName.</td>
</tr>
</tbody>
</table>

**ExtensionDefinition**

The ExtensionDefinition class defines and groups additional attributes. This type is not applicable when the XML schema interchange is used, since XSD Complex Types already satisfy this requirement.

Table 8-8 presents the attributes and model associations for the ExtensionDefinition element:

**Table 8-8 – ExtensionDefinition attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>The name of the extension. This is used as a namespace to uniquely identify the extension content.</td>
</tr>
<tr>
<td>extensionAttributeDefinitions:</td>
<td>The specific attributes that make up the extension.</td>
</tr>
<tr>
<td>ExtensionDefinition [0..*]</td>
<td></td>
</tr>
</tbody>
</table>
ExtensionAttributeDefinition

The ExtensionAttributeDefinition defines new attributes. This type is not applicable when the XML schema interchange is used; since the XSD mechanisms for supporting “AnyAttribute” and “Any” type already satisfy this requirement.

Table 8-9 presents the attributes for the ExtensionAttributeDefinition element:

Table 8-9 – ExtensionAttributeDefinition attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>The name of the extension attribute.</td>
</tr>
<tr>
<td>type: string</td>
<td>The type that is associated with the attribute.</td>
</tr>
<tr>
<td>isReference: boolean [0..1] = False</td>
<td>Indicates if the attribute value will be referenced or contained.</td>
</tr>
</tbody>
</table>

ExtensionAttributeValue

The ExtensionAttributeValue contains the attribute value. This type is not applicable when the XML schema interchange is used; since the XSD mechanisms for supporting “AnyAttribute” and “Any” type already satisfy this requirement.

Table 8-10 presents the model associations for the ExtensionAttributeValue element:

Table 8-10 – ExtensionAttributeValue model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>value: Element [0..1]</td>
<td>The contained attribute value, used when the associated ExtensionAttributeDefinition.isReference is false. The type of this Element must conform to the type specified in the associated ExtensionAttributeDefinition.</td>
</tr>
<tr>
<td>valueRef: Element [0..1]</td>
<td>The referenced attribute value, used when the associated ExtensionAttributeDefinition.isReference is true. The type of this Element must conform to the type specified in the associated ExtensionAttributeDefinition.</td>
</tr>
<tr>
<td>extensionAttributeDefinition: ExtensionAttributeDefinition</td>
<td>Defines the extension attribute for which this value is being provided.</td>
</tr>
</tbody>
</table>
Extensibility XML Schemas

Table 8-11 – Extension XML schema

```xml
<xsd:element name="extension" type="tExtension"/>
<xsd:complexType name="tExtension">
  <xsd:sequence>
    <xsd:element ref="documentation" minOccurs="0" maxOccurs="unbounded"/>
  </xsd:sequence>
  <xsd:attribute name="definition" type="xsd:QName"/>
  <xsd:attribute name="mustUnderstand" type="xsd:boolean" use="optional"/>
</xsd:complexType>
```

XML Example

This example shows a Task, defined the BPMN Core, being extended with Inputs and Outputs defined outside of the Core.

Table 8-12 – Example Core XML schema

```xml
<xsd:schema ...>
  ...
  <xsd:element name="task" type="tTask"/>
</xsd:schema>
8.2.4. External Relationships

It is the intention of this specification to cover the basic elements required for the construction of semantically rich and syntactically valid Process models to be used in the description of Processes, Choreographies and business operations in multiple levels of abstraction. As the specification indicates, extension capabilities enable the enrichment of the information described in BPMN and supporting models to be augmented to fulfill particularities of a given usage model. These extensions intention is to extend the semantics of a given BPMN Artifact to provide specialization of intent or meaning.

Process models do not exist in isolation and generally participate in larger, more complex business and system development Processes. The intention of the following specification element is to enable BPMN Artifacts to Proposal for:

Table 8-13 – Example Extension XML schema

```xml
<xsd:schema ...>
...
<xsd:group name="dataRequirements">
  <xsd:sequence>
    <xsd:element ref="dataInput" minOccurs="0" maxOccurs="unbounded" />
    <xsd:element ref="dataOutput" minOccurs="0" maxOccurs="unbounded" />
    <xsd:element ref="inputSet" minOccurs="0" maxOccurs="unbounded" />
    <xsd:element ref="outputSet" minOccurs="0" maxOccurs="unbounded" />
  </xsd:sequence>
</xsd:group>
... 
</xsd:schema>
```

Table 8-14 – Sample XML instance

```xml
<bpmn:definitions id="ID_1" ...>
...
<bpmn:extension mustUnderstand="true" definition="bpmn:dataRequirements"/>
...
<bpmn:task name="Retrieve Customer Record" id="ID_2">
  <bpmn:dataInput name="Order Input" id="ID_3">
    <bpmn:typeDefinition typeRef="bo:Order" id="ID_4"/>
  </bpmn:dataInput>
  <bpmn:dataOutput name="Customer Record Output" id="ID_5">
    <bpmn:typeDefinition typeRef="bo:CustomerRecord" id="ID_6"/>
  </bpmn:dataOutput>
  <bpmn:inputSet name="Inputs" id="ID_7" dataInputRefs="ID_3"/>
  <bpmn:outputSet name="Outputs" id="ID_8" dataOutputRefs="ID_5"/>
</bpmn:task>
...
</bpmn:definitions>
```
be integrated in these development Processes via the specification of a non-intrusive identity/relationship model between BPMN Artifacts and elements expressed in any other addressable domain model.

The ‘identity/relationship’ model it is reduced to the creation of families of typed relationships that enable BPMN and non-BPMN Artifacts to be related in non intrusive manner. By simply defining ‘relationship types’ that can be associated with elements in the BPMN Artifacts and arbitrary elements in a given addressable domain model, it enables the extension and integration of BPMN models into larger system/development Processes.

It is that these extensions will enable, for example, the linkage of ‘derivation’ or ‘definition’ relationships between UML artifacts and BPMN Artifacts in novel ways. So, a UML use case could be related to a Process element in the BPMN specification without affecting the nature of the Artifacts themselves, but enabling different integration models that traverse specialized relationships.

Simply, the model enables the external specification of augmentation relationships between BPMN Artifacts and arbitrary relationship classification models, these external models, via traversing relationships declared in the external definition allow for linkages between BPMN elements and other structured or non-structured metadata definitions.

The UML model for this specification follow a simple extensible pattern as shown below; where named relationships can be established by referencing objects that exist in their given namespaces.

![Figure 8-7 – External Relationship Metamodel](image-url)
The `Relationship` element inherits the attributes and model associations of `BaseElement` (see Table 8-5). Table 8-15 presents the additional attributes for the `Relationship` element:

**Table 8-15 – Relationship attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>type</code>: string</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td><code>direction</code>: RelationshipDirection {none</td>
<td>forward</td>
</tr>
<tr>
<td><code>sources</code>: Element [1..*]</td>
<td>This association defines artifacts that are augmented by the relationship.</td>
</tr>
<tr>
<td><code>targets</code>: Element [1..*]</td>
<td>This association defines artifacts used to extend the semantics of the source element(s).</td>
</tr>
</tbody>
</table>

In this manner, you can, for example, create relationships between different artifacts that enable external annotations used for (for example) traceability, derivation, arbitrary classifications, etc.

An example where the ‘reengineer’ relationship is shown between elements in a Visio™ artifact and a BPMN Artifact:

**Table 8-16 – Reengineer XML schema**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<definitions targetNamespace="" typeLanguage="" id="a123" expressionLanguage=""
   xsi:schemaLocation="http://www.omg.org/bpmn20 Core-Common.xsd"
   xmlns="http://www.omg.org/bpmn20"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xmlns:src="http://www.example.org/Processes/Old"
   xmlns:tgt="http://www.example.org/Processes/New">

  <import importType="http://office.microsoft.com/visio" location="OrderConfirmationProcess.vsd"
    namespace="http://www.example.org/Processes/Old"/>

  <import importType="http://www.omg.org/bpmn20" location="OrderConfirmationProcess.xml"
    namespace="http://www.example.org/Processes/New"/>

  <relationship type="reengineered" id="a234" direction="both">
    <documentation>An as-is and to-be relationship. The as-is model is expressed as a Visio diagram.
    The re-engineered process has been split in two and is captured in BPMN 2.0 format.</documentation>
    <source ref="src:OrderConfirmation"/>
    <target ref="tgt:OrderConfirmation_PartI"/>
    <target ref="tgt:OrderConfirmation_PartII"/>
  </relationship>
</definitions>
```
8.2.5. Root Element

RootElement is the abstract super class for all BPMN elements that are contained within Definitions. When contained within Definitions, these elements have their own defined life-cycle and are not deleted with the deletion of other elements. Examples of concrete RootElements include Collaboration, Process, and Choreography. Depending on their use, RootElements can be referenced by multiple other elements (i.e., they can be reused). Some RootElements may be contained within other elements instead of Definitions. This is done to avoid the maintenance overhead of an independent life-cycle. For example, an EventDefinition may be contained in a Process since it may be only required there. In this case the EventDefinition would be dependent on the tool life-cycle of the Process.

The RootElement element inherits the attributes and model associations of BaseElement (see Table 8-5), but does not have any further attributes or model associations.

8.2.6. Foundation Package XML Schemas

Table 8-17 – BaseElement XML schema

```
<xs:element name="baseElement" type="tBaseElement"/>
<xs:complexType name="tBaseElement" abstract="true">
  <xs:sequence>
    <xs:element ref="documentation" minOccurs="0" maxOccurs="unbounded"/>
    <xs:element ref="category" minOccurs="0" maxOccurs="unbounded"/>
    <xs:any namespace="##other" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
  </xs:sequence>
  <xs:attribute name="id" type="xsd:ID" use="required"/>
  <xs:anyAttribute namespace="##other" processContents="lax"/>
</xs:complexType>

<xs:element name="baseElementWithMixedContent" type="tBaseElementWithMixedContent"/>
<xs:complexType name="tBaseElementWithMixedContent" abstract="true" mixed="true">
  <xs:sequence>
    <xs:element ref="documentation" minOccurs="0" maxOccurs="unbounded"/>
    <xs:element ref="category" minOccurs="0" maxOccurs="unbounded"/>
    <xs:any namespace="##other" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
  </xs:sequence>
  <xs:attribute name="id" type="xsd:ID" use="required"/>
  <xs:anyAttribute namespace="##other" processContents="lax"/>
</xs:complexType>

<xs:element name="documentation" type="tDocumentation"/>
<xs:complexType name="tDocumentation" mixed="true">
  <xs:sequence>
    <xs:any namespace="##any" processContents="lax" minOccurs="0"/>
  </xs:sequence>
</xs:complexType>
```
8.3. Common Elements

The following sections define BPMN elements that may be used in more than one type of diagram (e.g., Process, Collaboration, Conversation, and Choreography).

8.3.1. Artifacts

BPMN provides modelers with the capability of showing additional information about a Process that is not directly related to the Sequence Flow or Message Flow of the Process.

At this point, BPMN provides three (3) standard Artifacts: Associations, Groups, and a Text Annotations. Additional Artifacts may be added to the BPMN specification in later versions. A modeler or modeling tool may extend a BPMN diagram and add new types of Artifacts to a Diagram. Any new Artifact must follow the Sequence Flow and Message Flow connection rules (listed below). Associations can be used to link Artifacts to Flow Objects (see page 87).
Figure 8-8 shows the Artifacts class diagram. When an Artifact is defined it is contained within a Collaboration or a FlowElementsContainer (a Process or Choreography).

Common Artifact Definitions

The following sections provide definitions that are common to all Artifacts.

Artifact Sequence Flow Connections

See “Sequence Flow Rules,” on page 64 for the entire set of objects and how they may be source or targets of Sequence Flow.

- An Artifact MUST NOT be a target for Sequence Flow.
- An Artifact MUST NOT be a source for Sequence Flow.

Artifact Message Flow Connections

See “Message Flow Rules,” on page 65 for the entire set of objects and how they may be source or targets of Message Flow.

- An Artifact MUST NOT be a target for Message Flow.
- An Artifact MUST NOT be a source for Message Flow.
Association

An Association is used to associate information and Artifacts with Flow Objects. Text and graphical non-Flow Objects can be associated with the Flow Objects and Flow. An Association is also used to show the Activity used for compensation. More information about compensation can be found page on 314.

- An Association line that MUST be drawn with a dotted single line (see Figure 8-9).
- The use of text, color, size, and lines for an Association MUST follow the rules defined in section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.

Figure 8-9 – An Association

Figure 8-10 – The Association Class Diagram

If there is a reason to put directionality on the Association then:

- A line arrowhead MAY be added to the Association line (see Figure 8-11).
- The directionality of the Association can be in one (1) direction or in both directions.
Figure 8-11 – A Directional Association

Note that directional Associations were used in BPMN 1.2 to show how Data Objects were inputs or outputs to Activities. In BPMN 2.0, a Data Association connector is used to show inputs and outputs (see page 228). A Data Association uses the same notation as a directed Association (as in Figure 8-11 above).

An Association is used to connect user-defined text (an Annotation) with a Flow Object (see Figure 8-12).

Figure 8-12 – An Association of Text Annotation

The Association element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-20 presents the additional attributes and model associations for an Association:

Table 8-20 – Association attributes and model associations

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>associationDirection</strong>: AssociationDirection = None (None</td>
<td>One</td>
</tr>
<tr>
<td><strong>sourceRef</strong>: BaseElement</td>
<td>The BaseElement that the Association is connecting from.</td>
</tr>
<tr>
<td><strong>targetRef</strong>: BaseElement</td>
<td>The BaseElement that the Association is connecting to.</td>
</tr>
</tbody>
</table>

Group

The Group object is an Artifact that provides a visual mechanism to group elements of a diagram informally. The grouping is tied to the Category supporting element (which is an attribute of all BPMN elements). That is, a Group is a visual depiction of a single Category. The graphical elements within the
Group will be assigned the Category of the Group. (Note -- Categories can be highlighted through other mechanisms, such as color, as defined by a modeler or a modeling tool).

- A Group is a rounded corner rectangle that MUST be drawn with a solid dashed line (as seen in Figure 8-13).
- The use of text, color, size, and lines for a Group MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.

![Figure 8-13 – A Group Artifact](image)

As an Artifact, a Group is not an Activity or any Flow Object, and, therefore, cannot connect to Sequence Flow or Message Flow. In addition, Groups are not constrained by restrictions of Pools and Lanes. This means that a Group can stretch across the boundaries of a Pool to surround Diagram elements (see Figure 8-14) often to identify Activities that exist within a distributed business-to-business transaction.

![Figure 8-14 – A Group around Activities in different Pools](image)
**Groups** are often used to highlight certain sections of a Diagram without adding additional constraints for performance—as a Sub-Process would. The highlighted (grouped) section of the Diagram can be separated for reporting and analysis purposes. **Groups** do not affect the flow of the Process.

**Figure 8-15** shows the **Group** class diagram.

![Group class diagram](image)

**Figure 8-15** – The Group class diagram

The **Group** element inherits the attributes and model associations of **BaseElement** (see Table 8-5). Table 8-21 presents the additional model associations for a **Group**:

**Table 8-21** – Group model associations

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
</table>
| categoryRef: Category [0..1] | The `categoryRef` attribute specifies the Category that the Group represents (Further details about the definition of a Category can be found on page 92).  
The name of the Category provides the label for the Group. The graphical elements within the boundaries of the Group will be assigned the Category. |
Category

Categories, which have user-defined semantics, can be used for documentation or analysis purposes. For example, FlowElements can be categorized has being customer oriented vs. support oriented. For example, the cost and time of each Category of each Activity can be calculated.

Groups are one way in which Categories of objects can be visually displayed on the diagram. That is, a Group is a visual depiction of a single Category. The graphical elements within the Group will be assigned the Category of the Group. The Category name appears on the diagram as the Group label. (Note -- Categories can be highlighted through other mechanisms, such as color, as defined by a modeler or a modeling tool). A single Category can be used for multiple Groups in a diagram.

The Category element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to RootElement. Table 8-22 displays the additional model associations of the Category element.

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>categoryValue: CategoryValue [0..&quot;]</td>
<td>The categoryValue attribute specifies one or more values of the Category. For example, the Category is “Region” then this Category could specifies values like “North”, “South”, “West” and “East.”</td>
</tr>
</tbody>
</table>

The Category element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-23 displays the attributes and model associations of the CategoryValue element.

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value: string</td>
<td>This attribute provides the value of the CategoryValue element.</td>
</tr>
<tr>
<td>category: Category [0..1]</td>
<td>The category attribute specifies the Category representing the Category as such and contains the CategoryValue. (Further details about the definition of a Category can be found on page 92.)</td>
</tr>
<tr>
<td>categorizedFlowElements: FlowElement [0..&quot;]</td>
<td>The FlowElements attribute identifies all of the elements (e.g., Events, Activities, Gateways, and Artifacts) that are within the boundaries of the Group.</td>
</tr>
</tbody>
</table>
Text Annotation

Text Annotations are a mechanism for a modeler to provide additional information for the reader of a BPMN Diagram.

- A Text Annotation is an open rectangle that MUST be drawn with a solid single line (as seen in Figure 8-16).
- The use of text, color, size, and lines for a Text Annotation MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.

The Text Annotation object can be connected to a specific object on the Diagram with an Association, but do not affect the flow of the Process. Text associated with the Annotation can be placed within the bounds of the open rectangle.

Figure 8-16 – A Text Annotation

The Text Annotation element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-24 presents the additional attributes for a Text Annotation:

Table 8-24 – Text Annotation attributes

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text: string</td>
<td>Text is an attribute that is text that the modeler wishes to communicate to the reader of the Diagram.</td>
</tr>
</tbody>
</table>

XML Schema for Artifacts

Table 8-25 – Artifact XML schema

    </xsd:complexContent>
</xsd:complexType>
<xsd:element name="text" type="tText"/>
<xsd:complexType name="tText" mixed="true">
    <xsd:sequence>
        <xsd:any namespace="##any" processContents="lax" minOccurs="0"/>
    </xsd:sequence>
</xsd:complexType>
```

8.3.2. Callable Element

CallableElement is the abstract super class of all Activities that have been defined outside of a Process or Choreography but which can be called (or reused) from within a Process or Choreography. It may reference Interfaces that define the service operations that it provides.

CallableElements are RootElements, which can be imported and used in other Definitions. When CallableElements (e.g., Process) are defined, they are contained within Definitions.

Figure 8-17 – CallableElement class diagram
The CallableElement inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to RootElement. Table 8-30 presents the additional attributes and model associations of the CallableElement:

**Table 8-30 – CallableElement attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td>supportedInterfacesRefs: Interface [0..*]</td>
<td>The Interfaces describing the external behavior provided by this element.</td>
</tr>
<tr>
<td>ioSpecification:</td>
<td>The InputOutputSpecification defines the inputs and outputs and the InputSets and OutputSets for the Activity.</td>
</tr>
<tr>
<td></td>
<td>ioBinding: InputOutputBinding [0..*]</td>
</tr>
<tr>
<td></td>
<td>The InputOutputBinding defines a combination of one InputSet and one OutputSet in order to bind this to an operation defined in an interface.</td>
</tr>
</tbody>
</table>

When a CallableElement is exposed as a Service, it has to define one or more InputOutputBinding elements. An InputOutputBinding element binds one Input and one Output of the InputOutputSpecification to an Operation of a Service Interface. Table 8-31 presents the additional model associations of the InputOutputBinding:

**Table 8-31 – InputOutputBinding model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputDataRef: DataInput</td>
<td>A reference to one specific DataInput defined as part of the InputOutputSpecification of the Activity.</td>
</tr>
<tr>
<td>outputDataRef: DataOutput</td>
<td>A reference to one specific DataOutput defined as part of the InputOutputSpecification of the Activity.</td>
</tr>
<tr>
<td>operationRef: Operation</td>
<td>A reference to one specific Operation defined as part of the Interface of the Activity.</td>
</tr>
</tbody>
</table>

**8.3.3. Correlation**

The concept of *Correlation* facilitates the association of a Message to a Send Task or Receive Task involved in a Conversation, a mechanism BPMN refers to as *instance routing*. It is a particular useful concept where there is no infrastructure support for *instance* routing. Note that this association can be viewed at multiple levels, namely the Conversation, Choreography, and Process level. However, the actual correlation happens during runtime (e.g. at the Process level). Correlations describe a set of predicates on a Message (generally on the application payload) that need to be satisfied in order for that Message to be associated to a distinct Send Task or Receive Task. By the same token, each Send Task and each Receive Task
participates in one or many Conversations. Furthermore, it identifies the Message it sends or receives and thereby establishes the relationship to one (or many) CorrelationKeys.

There are two, non-exclusive correlation mechanisms in place:

- In plain, key-based correlation, Messages that are exchanged within a Conversation are logically correlated by means of a joint CorrelationKey. That is, any Message that is sent or received within this Conversation needs to carry the value of the CorrelationKey instance within its payload. A CorrelationKey basically defines a (composite) key. The first Message that is initially sent or received initializes the CorrelationKey instance, i.e. assigns values to its CorrelationProperty instances which are the fields (partial keys) of the CorrelationKey. Follow-up Messages will have to match the CorrelationKey instance to be dispatched to this particular Conversation. As a Conversation may comprise different Messages that may be differently structured, each CorrelationProperty comes with as many extraction rules (CorrelationPropertyRetrievalExpression) for the respective partial key as there are different Messages.

- In context-based correlation, the Process context (i.e., its Data Objects and Properties) may dynamically influence the matching criterion. That is, a CorrelationKey may be complemented by a Process-specific CorrelationSubscription. A CorrelationSubscription aggregates as many CorrelationPropertyBindings as there are CorrelationProperties in the CorrelationKey. A CorrelationPropertyBinding relates to a specific CorrelationProperty and also links to a FormalExpression which denotes a dynamic extraction rule atop the Process context. At runtime, the CorrelationKey instance for a particular Conversation is populated (and dynamically updated) from the Process context using these FormalExpressions. In that sense, changes in the Process context may alter the correlation condition.
A `CorrelationKey` represents a composite key out of one (1) or many `CorrelationProperties` which essentially specify extraction `Expressions` atop `Messages`. As a result, each `CorrelationProperty` acts as a partial key for the correlation. For each `Message` that is received within a particular `Conversation`, the `CorrelationProperties` need to provide a `CorrelationPropertyRetrievalExpression` which references a `FormalExpression` to the...
Message payload. That is, for each Message (that is used in a Conversation) there is an Expression which extracts portions of the respective Message’s payload.

The CorrelationKey element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-32 displays the additional model associations of the CorrelationKey element.

Table 8-32 – CorrelationKey model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>conversation: Conversation</td>
<td>A reference to the specific Conversation this CorrelationKey applies to.</td>
</tr>
<tr>
<td>correlationPropertyRef:</td>
<td>The CorrelationProperties, representing the partial keys of this CorrelationKey</td>
</tr>
<tr>
<td>CorrelationProperty [0..*]</td>
<td></td>
</tr>
</tbody>
</table>

Key-based Correlation

Key-based correlation is a simple and efficient form of correlation, where one or more keys are used to identify a Conversation. Any incoming Message can be matched against the CorrelationKey by extracting the CorrelationProperties from the Message according to the corresponding CorrelationPropertyRetrievalExpression and comparing the resulting composite key with the CorrelationKey instance for this Conversation. The idea is to use a joint Conversation “token” which is used (passed to and received from) and outgoing and incoming Message. Messages will be routed to the Conversation whose extracted composite key matches the respective CorrelationKey instance.

At runtime the first Send Task or Receive Task in a Conversation populates the CorrelationKey instance by extracting the values of the CorrelationProperties according to the CorrelationPropertyRetrievalExpression from the initially sent or received Message. Later in the Conversation, this CorrelationKey instance is used for the described matching procedure where from incoming Messages a composite key is extracted and used to identify the associated Conversation.

The CorrelationProperty element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to RootElement. Table 8-33 displays the additional model associations of the CorrelationProperty element.

Table 8-33 – CorrelationProperty model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>correlationPropertyRetrievalExpression:</td>
<td>The CorrelationPropertyRetrievalExpressions for this CorrelationProperty, representing the associations of FormalExpressions (extraction paths) to specific Messages occurring in this Conversation.</td>
</tr>
<tr>
<td>CorrelationPropertyRetrievalExpression [1..*]</td>
<td></td>
</tr>
</tbody>
</table>
Table 8-34 – CorrelationPropertyRetrievalExpression model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>messagePath: FormalExpression</td>
<td>The FormalExpression that defines how to extract a CorrelationProperty from the Message payload</td>
</tr>
<tr>
<td>message: Message</td>
<td>The specific Message the FormalExpression extracts the CorrelationProperty from.</td>
</tr>
</tbody>
</table>

Context-based Correlation

Context-based correlation is a more expressive form of correlation on top of key-based correlation. In addition to implicitly populating the CorrelationKey instance from the first sent or received Message, another mechanism relates the CorrelationKey to the Process context. That is, a Process may provide a CorrelationSubscription which acts as the Process-specific counterpart to a specific CorrelationKey. In this way, a Conversation may additionally refer to explicitly updateable Process context data to determine whether or not a Message shall be received. At runtime, the CorrelationKey instance holds a composite key that is dynamically calculated from the Process context and automatically updated whenever the underlying Data Objects or Properties change.

CorrelationPropertyBindings represent the partial keys of a CorrelationSubscription where each relates to a specific CorrelationProperty in the associated CorrelationKey. A FormalExpression defines how that CorrelationProperty instance is populated and updated at runtime from the Process context (i.e., its Data Objects and Properties).

The CorrelationSubscription element inherits the attributes and model associations of BaseElement (see Table 8-5) Table 8-35 displays the additional model associations of the CorrelationSubscription element.

Table 8-35 – CorrelationSubscription model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process: Process</td>
<td>The Process that this CorrelationSubscription belongs to.</td>
</tr>
<tr>
<td>correlationKeyRef: CorrelationKey</td>
<td>The CorrelationKey this CorrelationSubscription refers to.</td>
</tr>
<tr>
<td>correlationPropertyBinding: CorrelationPropertyBinding [0..*]</td>
<td>The bindings to specific CorrelationProperties and FormalExpressions (extraction rules atop the Process context).</td>
</tr>
</tbody>
</table>

The CorrelationPropertyBinding element inherits the attributes and model associations of BaseElement (see Table 8-5) Table 8-36 displays the additional model associations of the CorrelationPropertyBinding element.
Table 8-36 – CorrelationPropertyBinding model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataPath: FormalExpression</td>
<td>The FormalExpression that defines the extraction rule atop the Process context.</td>
</tr>
<tr>
<td>correlationPropertyRef:</td>
<td>The specific CorrelationProperty, this CorrelationPropertyBinding refers to.</td>
</tr>
<tr>
<td>CorrelationProperty</td>
<td></td>
</tr>
</tbody>
</table>

At runtime, the correlation mechanism works as follows: When a Process instance is created the CorrelationKey instances of all Conversations are initialized with some initial values that specify to correlate any incoming Message for these Conversations. A SubscriptionProperty is updated whenever any of the Data Objects or Properties changes that are referenced from the respective FormalExpression. As a result, incoming Messages are matched against the now populated CorrelationKey instance. Later in the Process run, the SubscriptionProperties may, again, change and implicitly change the correlation criterion. Alternatively, the established mechanism of having the first Send Task or Receive Task populate the CorrelationKey instance applies.

**XML Schema for Correlation**

Table 8-37 – Correlation Key XML schema

            </xs:sequence>
        </xs:extension>
    </xs:complexContent>
</xs:complexType>
```
8.3.4. Conversation Association

A ConversationAssociation is used within Collaborations and Choreographies to apply a reusable Conversation to Message Flow of those diagrams.

A ConversationAssociation is used when a diagram references a Conversation to provide Message correlation information and/or to logically group Message Flow. There are two (2) usages of ConversationAssociation. It is used when:

- A Collaboration references a reusable Conversation. The Message Flow of the Collaboration are grouped by the ConversationAssociation. A tool can use the correlationKey of the Conversation (also referenced) or allow the user to group the Message Flow of the Collaboration.

- A Choreography references a reusable Conversation. The Message Flow of the Choreography are grouped by the ConversationAssociation. A tool can use the correlationKey of the Conversation (also referenced) or allow the user to group the Message Flow of the Choreography.

![Figure 8-19 – The ConversationAssociation class diagram]

The ConversationAssociation element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 9-1 presents the additional model associations for the ConversationAssociation element:
Table 8-42 – ConversationAssociation Model Associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>conversationRef</td>
<td>This attribute references the Conversation that is being applied to the Collaboration or Choreography.</td>
</tr>
<tr>
<td>correlationKeyRef</td>
<td>This attribute references a correlationKey in the referenced Conversation that is being applied to the Collaboration or Choreography.</td>
</tr>
<tr>
<td>messageFlowRefs</td>
<td>The messageFlowRefs are used to identify the Message Flow within the Collaboration or Choreography that are to be grouped by the referenced Conversation. This grouping can be done automatically through the referenced CorrelationKey of the Conversation (matching the CorrelationKey to the Messages of the Message Flow) or done through user selection if a CorrelationKey has not been defined or referenced.</td>
</tr>
</tbody>
</table>

8.3.5. Error

An Error represents the content of an Error Event or the Fault of a failed Operation. A ItemDefinition is used to specify the structure of the Error. An Error is generated when there is a critical problem in the processing of an Activity or when the execution of an Operation failed.

Figure 8-20 – Error class diagram
The Error element inherits the attributes and model associations of BaseElement (see Table 8-5), through its relationship to RootElement. Table 8-43 presents the additional model associations of the Error element:

**Table 8-43 – Error model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>structureRef</code></td>
<td>An ItemDefinition is used to define the “payload” of the Error.</td>
</tr>
</tbody>
</table>

### 8.3.6. Events

An Event is something that “happens” during the course of a Process. These Events affect the flow of the Process and usually have a cause or an impact. The term “event” is general enough to cover many things in a Process. The start of an Activity, the end of an Activity, the change of state of a document, a Message that arrives, etc., all could be considered Events. However, BPMN has restricted the use of Events to include only those types of Events that will affect the sequence or timing of Activities of a Process.

![Figure 8-21 – Event class diagram](image-url)
The Event element inherits the attributes and model associations of Flow Element (see Table 8-45), but adds no additional attributes or model associations:

The details for the types of Events (Start, Intermediate, and End) are defined in the Section “Event Definitions” on page 266.

8.3.7. Expressions

The Expression class is used to specify an expression using natural-language text. These expressions are not executable. The natural language text is captured using the documentation attribute, inherited from BaseElement.

Expression inherits the attributes and model associations of BaseElement (see Table 8-5), but adds no additional attributes or model associations.

Expressions are used in many places within BPMN to extract information from the different elements, normally data elements. The most common usage is when modeling decisions, where conditional expressions are used to direct the flow along specific paths based on some criteria.

BPMN supports underspecified expressions, where the logic is captured as natural-language descriptive text. It also supports formal expressions, where the logic is captured in an executable form using a specified expression language.

Figure 8-22 – Expression class diagram
**Expression**

The *Expression* class is used to specify an expression using natural-language text. These expressions are not executable and are considered underspecified.

The definition of an expression can be done in two ways: it can be contained where it is used, or it can be defined at the *Process* level and then referenced where it is used.

The *Expression* element inherits the attributes and model associations of *BaseElement* (see [Table 8-5]), but does not have any additional attributes or model associations.

**Formal Expression**

The *FormalExpression* class is used to specify an executable expression using a specified expression language. A natural-language description of the expression can also be specified, in addition to the formal specification.

The default expression language for all expressions is specified in the *Definitions* element, using the *expressionLanguage* attribute. It can also be overridden on each individual *FormalExpression* using the same attribute.

The *FormalExpression* element inherits the attributes and model associations of *BaseElement* (see [Table 8-5]) through the *Expression* element. [Table 8-44] presents the additional attributes and model associations of the *FormalExpression*:

**Table 8-44 – FormalExpression attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>language: string [0..1]</td>
<td>Overrides the expression language specified in the Definitions.</td>
</tr>
<tr>
<td>body: Element</td>
<td>The body of the expression. The body of the <em>Expression</em> would be specified as element content. For example:  &lt;formalExpression id=&quot;ID_2&quot;&gt; count(../dataObject[id=&quot;CustomerRecord_1&quot;]/emailAddress) &gt; 0  &lt;evaluatesToType id=&quot;ID_3&quot; typeRef=&quot;xsd:boolean&quot;/&gt; &lt;/formalExpression&gt;</td>
</tr>
<tr>
<td>evaluatesToTypeRef: ItemDefinition</td>
<td>The type of object that this <em>Expression</em> returns when evaluated. For example, <em>conditional</em> Expressions evaluate to a boolean.</td>
</tr>
</tbody>
</table>
8.3.8. Flow Element

FlowElement is the abstract super class for all elements that can appear in a Process flow, which are FlowNodes (see page 33), which consist of Activities (see page 59), Choreography Activities (see page 349), Gateways (see page 10), and Events (see page 103), Data Objects (see page 113), Data Associations (see page 228), and Sequence Flow (see page 29).

Figure 8-23 – FlowElement class diagram

The FlowElement element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-45 presents the additional attributes and model associations of the FlowElement element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td>auditing: Auditing [0..1]</td>
<td>A hook for specifying audit related properties. Auditing can only be defined for a Process.</td>
</tr>
<tr>
<td>monitoring: Monitoring [0..1]</td>
<td>A hook for specifying monitoring related properties. Monitoring can only be defined for a Process.</td>
</tr>
</tbody>
</table>

Proposal for:
Business Process Model and Notation (BPMN), v2.0
8.3.9. Flow Elements Container

`FlowElementsContainer` is an abstract super class for BPMN diagrams (or views) and defines the superset of elements that are contained in those diagrams. Basically, a `FlowElementsContainer` contains `FlowElements`, which are `Events` (see page 103), Gateways (see page 110), Sequence Flow (see page 129), Activities (see page 159), and Choreography Activities (see page 349).

There are four (4) types of `FlowElementsContainers` (see Figure 8-24): Process, Sub-Process, Choreography, and Choreography Sub-Process.

![Figure 8-24 – FlowElementContainers class diagram](image-url)
The FlowElementsContainer element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-46 presents the additional model associations of the FlowElementsContainer element:

**Table 8-46 – FlowElementsContainer model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>flowElements: FlowElement [0..*]</td>
<td>This association specifies the particular flow elements contained in a FlowElementContainer. Flow elements are Events, Gateways, Sequence Flow, Activities, Data Objects, Data Associations, and Choreography Activities. Note that: • Choreography Activities MUST NOT be included as a flowElement for a Process • Activities, Data Associations, and Data Objects MUST NOT be included as a flowElement for a Choreography.</td>
</tr>

</table>

**8.3.10. Gateways**

Gateways are used to control how the Process flows (how Tokens flow) through Sequence Flow as they converge and diverge within a Process. If the flow does not need to be controlled, then a Gateway is not needed. The term “gateway” implies that there is a gating mechanism that either allows or disallows passage through the Gateway— that is, as tokens arrive at a Gateway, they can be merged together on input and/or split apart on output as the Gateway mechanisms are invoked.

Gateways, like Activities, are capable of consuming or generating additional control tokens, effectively controlling the execution semantics of a given Process. The main difference is that Gateways do not represent ‘work’ being done and they are considered to have zero effect on the operational measures of the Process being executed (cost, time, etc.).

The Gateway controls the flow of both diverging and converging Sequence Flow. That is, a single Gateway could have multiple input and multiple output flows. Modelers and modeling tools may want to enforce a best practice of a Gateway only performing one of these functions. Thus, it would take two sequential Gateways to first converge and then to diverge the Sequence Flow.
The details for the types of Gateways (Exclusive, Inclusive, Parallel, Event-Based, and Complex) is defined on page 295 for Processes and on page 375 for Choreographies.

The Gateway class is an abstract type. Its concrete subclasses define the specific semantics of individual Gateway types, defining how the Gateway behaves in different situations.

The Gateway element inherits the attributes and model associations of FlowElement (see Table 8-45). Table 8-47 presents the additional attributes of the Gateway element:

**Table 8-47 – Gateway attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>

<tr>
<td>unspecified: There are no constraints. The Gateway MAY have any number of incoming and outgoing Sequence Flow.</td>
<td></td>
</tr>
<tr>
<td>converging: This Gateway MAY have multiple incoming Sequence Flow but MUST have no more than one outgoing SequenceFlow.</td>
<td></td>
</tr>
<tr>
<td>diverging: This Gateway MAY have multiple outgoing Sequence Flow but MUST have no more than one incoming Sequence Flow.</td>
<td></td>
</tr>
<tr>
<td>mixed: This Gateway contains multiple outgoing and multiple incoming Sequence Flow.</td>
<td></td>
</tr>
</tbody>
</table>
8.3.11. Interaction Specification

The InteractionSpecification element is a superclass for all elements that require definition about interactions between Participants. Specifically, the InteractionSpecification element defines a list of Participants and Message Flow. The elements that inherit from InteractionSpecification include Collaboration, Choreography, and Conversation.

Figure 8-26 – InteractionSpecification class diagram

The InteractionSpecification element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-48 presents the attributes and model associations of the InteractionSpecification element:

Table 8-48 – InteractionSpecification attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>participants: Participant [0..*]</td>

</tr>
<tr>
<td>messageFlow: Message Flow [0..*]</td>
<td>This provides the list of Message Flow that are used in the InteractionSpecification</td>
</tr>
</tbody>
</table>
8.3.12. Item Definition

BPMN elements, such as DataObjects and Messages, represent items that are manipulated, transferred, transformed or stored during Process flows. These items can be either physical items, such as the mechanical part of a vehicle, or information items such the catalog of the mechanical parts of a vehicle.

An important characteristics of items in Process is their structure. BPMN does not require a particular format for this data structure, but it does designate XML Schema as its default. The structure attribute references the actual data structure.

The default format of the data structure for all elements can be specified in the Definitions element using the typeLanguage attribute. For example, a typeLanguage value of [http://www.w3.org/2001/XMLSchema](http://www.w3.org/2001/XMLSchema) indicates that the data structures using by elements within that Definitions are in the form of XML Schema types. If unspecified, the default is XML schema. An Import is used to further identify the location of the data structure (if applicable). For example, in the case of data structures contributed by an XML schema, an Import would be used to specify the file location of that schema.

Structure definitions are always defined as separate entities, so they cannot be inlined in one of their usages. You will see that in every mention of structure definition there is a “reference” to the element. This is why this class inherits from RootElement.

An ItemDefinition element can specify an import reference where the proper definition of the structure is defined.

In cases where the data structure represents a collection, the multiplicity can be projected into the attribute isCollection. If this attribute is set to “true”, but the actual type is not a collection type, the model is considered as invalid. BPMN compliant tools might support an automatic check for these inconsistencies and report this as an error. The default value for this element is “false”.

The itemKind attribute specifies the nature of an item which can be a physical or an information item.

Figure 8-27 shows the ItemDefinition class diagram. When a ItemDefinition is defined it is contained in Definitions.
The ItemDefinition element inherits the attributes and model associations BaseElement (see Table 8-5) through its relationship to RootElement. Table 8-49 presents the additional attributes and model associations for the ItemDefinition element:

**Table 8-49 – ItemDefinition attributes & model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>itemKind: ItemKind = “Information” (Information</td>
<td>Physical)</td>
</tr>
<tr>
<td>structure: Element [0..1]</td>
<td>The concrete data structure to be used.</td>
</tr>
<tr>
<td>import: Import [0..1]</td>
<td>Identifies the location of the data structure and its format. If the importType attribute is left unspecified, the typeLanguage specified in the Definitions that contains this ItemDefinition is assumed.</td>
</tr>
<tr>
<td>isCollection: boolean = False</td>
<td>Setting this flag to true indicates that the actual data type is a collection.</td>
</tr>
</tbody>
</table>
### 8.3.13. Message

A Message represents the content of a communication between two Participants. In BPMN 2.0, a Message is a graphical object (it was a supporting element in BPMN 1.2). An ItemDefinition is used to specify the Message structure.

When displayed in a diagram:

- In a Message is a rectangle with converging diagonal lines in the upper half of the rectangle to give the appearance of an envelope (see Figure 8-28). It MUST be drawn with a single thin line.
- The use of text, color, size, and lines for a Task MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.

![Figure 8-28 – A Message](image)

In addition, when used in a Choreography Diagram more than one Message may be used for a single Choreography Task or a Choreography Sub-Process. In this case, it is important to know the first (initiating) Message of the interaction. For return (non-initiating) Messages the symbol of the Message is shaded with a light fill (see Figure 8-29).

![Figure 8-29 – An non-initiating Message](image)

- Any Message that is after first on the list of Messages for a Choreography Task or a Choreography Sub-Process MUST be shaded with a light fill.

In a Collaboration, the communication itself is represented by a Message Flow (see the Section “Message Flow” below for more details). The Message can be displayed as attached (Associated) to a Message Flow in a Collaboration (see Figure 8-30 and Figure 8-31).
Figure 8-30 –Messages shown Associated with Message Flow

Figure 8-31 –Messages Association overlapping Message Flow

In a Choreography, the communication is represented by a Choreography Task (see page 150). The Message can be displayed as Associated with a Choreography Task in a Choreography (see
In a Process that is not used in a Collaboration, the communication is not displayed, but a Message can be defined for Activities that send and receive Messages (such as a Send Task—see Figure 8-33). Note that the display of Messages in a Process, Collaboration, or Choreography is optional.

Figure 8-33 –Messages shown Associated with a Send Task

Figure 8-34 displays the class diagram showing the attributes and model associations for the Message element.
The Message element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to RootElement. Table 8-50 presents the additional attributes and model associations for the Message element:

Table 8-50 – Message attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>Name is a text description of the Message</td>
</tr>
<tr>
<td>structureRef: ItemDefinition [0..1]</td>
<td>An ItemDefinition is used to define the “payload” of the Message.</td>
</tr>
</tbody>
</table>
8.3.14. Message Flow

A Message Flow is used to show the flow of Messages between two Participants that are prepared to send and receive them.

- A Message Flow MUST connect two separate Pools. They connect either to the Pool boundary or to Flow Objects within the Pool boundary. They MUST NOT connect two objects within the same Pool.
- A Message Flow is a line with an open circle line start and an open arrowhead line end that MUST be drawn with a dashed single line (see Figure 8-35).
- The use of text, color, size, and lines for a Pool MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.

Figure 8-35 – A Message Flow

In Collaboration Diagrams (the view showing the Choreography Process Combined with Orchestration Processes), the Message Flow can be extended to show the Message that is passed from one Participant to another (see Figure 8-36).

Figure 8-36 – A Message Flow with an Attached Message

If a Choreography is included in the Collaboration, then the Message Flow will “pass-through” a Choreography Task as it connects from one Participant to another (see Figure 8-37).
Figure 8-37 – A Message Flow passing through a Choreography Task

Figure 8-38 displays the class diagram of Message Flow and its relationships to other BPMN elements. When a Message Flow is defined it is contained either within a Collaboration, a Choreography Task, or a GlobalChoreographyTask.
Figure 8-38 – The Message Flow Class Diagram

The Message Flow element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-51 presents the additional attributes and model associations for the Message Flow element:

Table 8-51 – Message Flow attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>Name is a text description of the Message Flow.</td>

<td>The MessageFlowNode that the Message Flow is connecting to. Of the types of MessageFlowNode, only Pools/Participants, Activities, and Events can be the target.</td>
</tr>
<tr>
<td>messageRef: Message [0..1]</td>
<td>The messageRef model association defines the Message that is passed via the Message Flow. See page 112 for more details.</td>
</tr>
</tbody>
</table>
Message Flow Node

The `MessageFlowNode` element is used to provide a single element as the source and target `Message Flow` associations (see Figure 8-38, above) instead of the individual associations of the elements that can connect to `Message Flow` (see the section above). Only the `Pool/Participant`, `Activity`, and `Event` elements can connect to `Message Flow` and thus, these elements are the only ones that are sub-classes of `MessageFlowNode`.

The `MessageFlowNode` element does not have any attributes or model associations and does not inherit from any other BPMN element. Since `Pools/Participants`, `Activities`, and `Events` have their own attributes, model associations, and inheritances, additional attributes and model associations for the `MessageFlowNode` element are not necessary.

Message Flow Associations

These elements are used to do mapping between two elements that both contain `Message Flow`. The `MessageFlowAssociation` provides the mechanism to match up the `Message Flow`.

A `MessageFlowAssociation` is used when an (outer) diagram with `Message Flow` contains an (inner) diagram that also has `Message Flow`. There are three (3) usages of `MessageFlowAssociation`. It is used when:

- A Collaboration references a Choreography for inclusion between the Collaboration’s Pools (Participants). The `Message Flow` of the Choreography (the inner diagram) need to be mapped to the `Message Flow` of the Collaboration (the outer diagram).

- A Collaboration references a Conversation that contains `Message Flow`. The `Message Flow` of the Conversation may serve as a partial requirement for the Collaboration. Thus, the `Message Flow` of the Conversation (the inner diagram) need to be mapped to the `Message Flow` of the Collaboration (the outer diagram).

- A Choreography references a Conversation that contains `Message Flow`. The `Message Flow` of the Conversation may serve as a partial requirement for the Choreography. Thus, the `Message Flow` of the Conversation (the inner diagram) need to be mapped to the `Message Flow` of the Choreography (the outer diagram).
Figure 8-39 shows the class diagram for the MessageFlowAssociation element.

The MessageFlowAssociation element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-53 presents the additional model associations for the MessageFlowAssociation element:

Table 8-52 – MessageFlowAssociation attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>innerMessageFlowRef: Message Flow</td>
<td>This attribute defines the Message Flow of the referenced element (e.g., a Choreography to be used in a Collaboration) that will be mapped to the parent element (e.g., the Collaboration).</td>
</tr>
<tr>
<td>outerMessageFlowRef: Message Flow</td>
<td>This attribute defines the Message Flow of the parent element (e.g., a Collaboration references a Choreography) that will be mapped to the referenced element (e.g., the Choreography).</td>
</tr>
</tbody>
</table>
8.3.15. Participants

A Participant represents a specific PartnerEntity (e.g., a company) and/or a more general PartnerRole (e.g., a buyer, seller, or manufacturer) that Participants in a Collaboration. A Participant is often responsible for the execution of the Process enclosed in a Pool; however, a Pool may be defined without a Process.

Figure 8-40 displays the class diagram of the Participant and its relationships to other BPMN elements. When Participants are defined they are contained within an InteractionSpecification, which includes the sub-types of Collaboration, a Choreography, a Conversation, a Global Communication, or a GlobalChoreographyTask.

![Figure 8-40 – The Participant Class Diagram](image-url)
The *Participant* element inherits the attributes and model associations of *BaseElement* (see Table 8-5). Table 8-53 presents the additional attributes and model associations for the *Participant* element:

**Table 8-53 – Participant attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>Name is a text description of the <em>Participant</em>. The name of the <em>Participant</em> can be displayed directly or it can be substituted by the associated PartnerRole or PartnerEntity. Potentially, both the PartnerEntity name and PartnerRole name can be displayed for the <em>Participant</em>.</td>
</tr>
<tr>
<td>processRef: Process [0..1]</td>
<td>The processRef attribute identifies the Process that the <em>Participant</em> uses in the Collaboration. The Process will be displayed within the <em>Participant</em>’s Pool.</td>
</tr>
<tr>
<td>partnerRoleRef: PartnerRole [0..1]</td>
<td>The partnerRoleRef attribute identifies a PartnerRole that the <em>Participant</em> plays in the Collaboration. Both a PartnerRole and a PartnerEntity MAY be defined for the <em>Participant</em>.</td>
</tr>
<tr>
<td>partnerEntityRef: PartnerEntity [0..1]</td>
<td>The partnerEntityRef attribute identifies a PartnerEntity that the <em>Participant</em> plays in the Collaboration. Both a PartnerRole and a PartnerEntity MAY be defined for the <em>Participant</em>.</td>
</tr>
<tr>
<td>interfaceRef: Interface [0..*]</td>
<td>This association defines Interfaces that a <em>Participant</em> supports. The definition of Interfaces is provided on page 140.</td>
</tr>
<tr>
<td>participantMultiplicity: participantMultiplicity [0..1]</td>
<td>The participantMultiplicityRef model association is used to define <em>Participants</em> that represent more than one (1) instance of the <em>Participant</em> for a given interaction. See the next section for more details on ParticipantMultiplicity.</td>
</tr>
<tr>
<td>endpointRefs: EndPoint [0..*]</td>
<td>This attribute is used to specify the address (or endpoint reference) of concrete services realizing the <em>Participant</em>.</td>
</tr>
</tbody>
</table>

**PartnerEntity**

A *PartnerEntity* is one of the possible types of *Participant* (see the section above).
The `PartnerEntity` element inherits the attributes and model associations of `BaseElement` (see Table 8-5). Table 8-54 presents the additional attributes and model associations for the `PartnerEntity` element:

**Table 8-54 – PartnerEntity attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>Name is a text description of the <code>PartnerEntity</code>.</td>
</tr>
</tbody>
</table>

**PartnerRole**

A `PartnerRole` is one of the possible types of `Participant` (see the section above).

The `PartnerRole` element inherits the attributes and model associations of `BaseElement` (see Table 8-5). Table 8-55 presents the additional attributes and model associations for the `PartnerRole` element:

**Table 8-55 – PartnerRole attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>Name is a text description of the <code>PartnerRole</code>.</td>
</tr>
</tbody>
</table>

**Participant Multiplicity**

`ParticipantMultiplicity` is used to define the multiplicity of a `Participant`.

For example, a manufacturer may request a quote from multiple suppliers in a `Choreography`.

![Figure 8-41 – A Pool with a Multiple Participant](image)

Proposal for:  
Business Process Model and Notation (BPMN), v2.0
The following figure shows the Participant class diagram.

![Participant class diagram](image)

**Figure 8-42 – The Participant Multiplicity class diagram**

When the minimum attribute of the ParticipantMultiplicity element has been set by the modeler, then the multi-instance marker will be displayed in bottom center of the Pool (Participant – see Figure 8-41) or the Participant Band of a Choreography Activity (see page 356).

Table 8-56 presents the attributes for the ParticipantMultiplicity element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>minimum: integer [0..1] = 2</td>
<td>The minimum attribute defines minimum number of Participants that MUST be involved in the Collaboration. The value of minimum MUST be two (2) or greater.</td>
</tr>
<tr>
<td>maximum: integer [0..1] = 2</td>
<td>The maximum attribute defines maximum number of Participants that MAY be involved in the Collaboration. The value of maximum MUST be two (2) or greater.</td>
</tr>
</tbody>
</table>

Table 8-57 presents the Instance attributes of the ParticipantMultiplicity element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>numParticipants: integer [0..1]</td>
<td>The current number of the multiplicity of the Participant for this Choreography or Collaboration Instance.</td>
</tr>
</tbody>
</table>

**ParticipantAssociation**

These elements are used to do mapping between two elements that both contain Participants. There are situations where the Participants in different diagrams may be defined differently because they were developed independently, but represent the same thing. The ParticipantAssociation provides the mechanism to match up the Participants.

A ParticipantAssociation is used when an (outer) diagram with Participants contains an (inner) diagram that also has Participants. There are three (3) usages of ParticipantAssociation. It is used when:
• A Collaboration references a Choreography for inclusion between the Collaboration’s Pools (Participants). The Participants of the Choreography (the inner diagram) need to be mapped to the Participants of the Collaboration (the outer diagram).

• A Collaboration references a Process (within one of its Pools) and that Process contains a Call Activity that references another Process that has a definitional Collaboration. The Participants of the definitional Collaboration for the called Process (the inner diagram) need to be mapped to the Participants of the Collaboration (the outer diagram). Note that the outer Collaboration may be a definitional Collaboration for the referenced Process.

• A Choreography contains a Call Choreography Activity that references another Choreography. The Participants of the called Choreography (the inner diagram) need to be mapped to the Participants of the calling Choreography (the outer diagram).

A ParticipantAssociation can be owned by the outer diagram or one its elements. Figure 8-43 shows the class diagram for the ParticipantAssociation element.

![ParticipantAssociation class diagram](image)

**Figure 8-43 – ParticipantAssociation class diagram**
The ParticipantAssociation element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-58 presents the additional model associations for the ParticipantAssociation element:

Table 8-58 – ParticipantAssociation model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>innerParticipantRef: Participant</td>
<td>This attribute defines the Participant of the referenced element (e.g., a Choreography to be used in a Collaboration) that will be mapped to the parent element (e.g., the Collaboration).</td>
</tr>
<tr>
<td>outerParticipantRef: Participant</td>
<td>This attribute defines the Participant of the parent element (e.g., a Collaboration references a Choreography) that will be mapped to the referenced element (e.g., the Choreography).</td>
</tr>
</tbody>
</table>

8.3.16. Resources

The Resource class is used to specify resources that can be referenced by Activities. These Resources can be Human Resources as well as any other resource assigned to Activities during Process execution time.

The definition of a Resource is "abstract", because it only defines the Resource, without detailing how e.g. actual user IDs are associated at runtime. Multiple Activities can utilize the same Resource.

Every Resource can define a set of ResourceParameters. These parameters can be used at runtime to define query e.g. into an Organizational Directory. Every Activity referencing a parameterized Resource can bind values available in the scope of the Activity to these parameters.
The Resource element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to RootElement. Table 8-59 presents the additional model associations for the Resource element:

Table 8-59 – Resource attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>This attribute specifies the name of the Resource.</td>
</tr>
<tr>
<td>parameters: ResourceParameter [0..*]</td>
<td>This model association specifies the definition of the parameters required at runtime to resolve the Resource.</td>
</tr>
</tbody>
</table>

As mentioned before, the Resource can define a set of parameters to define a query to resolve the actual resources (e.g. user ids).

The ResourceParameter element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to RootElement. Table 8-59 presents the additional model associations for the ResourceParameter element:

Table 8-60 – ResourceParameter attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: String</td>
<td>Specifies the name of the query parameter.</td>
</tr>
<tr>
<td>type: Element</td>
<td>Specifies the type of the query parameter.</td>
</tr>
<tr>
<td>isRequired: Boolean</td>
<td>Specifies, if a parameter is optional or mandatory.</td>
</tr>
</tbody>
</table>

8.3.17. Sequence Flow

A Sequence Flow is used to show the order of Flow Elements in a Process or a Choreography. Each Sequence Flow has only one source and only one target. The source and target must be from the set of the following Flow Elements: Events (Start, Intermediate, and End), Activities (Task and Sub-Process; for Processes), Choreography Activities (Choreography Task and Choreography Sub-Process; for Choreographies), and Gateways.

- A Sequence Flow is line with a solid arrowhead that MUST be drawn with a solid single line (as seen in Figure 8-45).
- The use of text, color, size, and lines for a Task MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.

Figure 8-45 – A Sequence Flow
A Sequence Flow can optionally define a condition Expression, indicating that the token will be passed down the Sequence Flow only if the Expression evaluates to true. This Expression is typically used when the source of the Sequence Flow is a Gateway or an Activity.

- A conditional outgoing Sequence Flow from an Activity MUST be drawn with a mini-diamond marker at the beginning of the connector (as seen in Figure 8-46).
- If a conditional Sequence Flow is used from a source Activity, then there MUST be at least one other outgoing Sequence Flow from that Activity.
- Conditional outgoing Sequence Flow from a Gateway MUST NOT be drawn with a mini-diamond marker at the beginning of the connector.
- A source Gateway MUST NOT be of type Parallel or Event.

Figure 8-46 – A Conditional Sequence Flow

A Sequence Flow that has an Exclusive, Inclusive, or Complex Gateway or an Activity as its source can also be defined with as default. Such Sequence Flow will have a marker to show that it is a default flow. The default Sequence Flow is taken (a token is passed) only if all the other outgoing Sequence Flow from the Activity or Gateway are not valid (i.e., their condition Expressions are false)

- A default outgoing Sequence Flow MUST be drawn with a slash marker at the beginning of the connector (as seen in Figure 8-47).

Figure 8-47 – A Default Sequence Flow
The Sequence Flow element inherits the attributes and model associations of FlowElement (see Table 8-45). Table 8-61 presents the additional attributes and model associations of Sequence Flow element:

**Table 8-61 – SequenceFlow attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
</table>
| sourceRef: FlowNode | The FlowNode that the Sequence Flow is connecting from.  
For a Process: Of the types of FlowNode, only Activities, Gateways, and Events can be the source. However, Activities that are Event Sub-Processes are not allowed to be a source.  
For a Choreography: Of the types of FlowNode, only Choreography Activities, Gateways, and Events can be the source. |
| targetRef: FlowNode | The FlowNode that the Sequence Flow is connecting to.  
For a Process: Of the types of FlowNode, only Activities, Gateways, and Events can be the target. However, Activities that are Event Sub-Processes are not allowed to be a target.  
For a Choreography: Of the types of FlowNode, only Choreography Activities, Gateways, and Events can be the target. |
### conditionExpression: Expression [0..1]

An optional Boolean Expression that acts as a gating condition. A token will only be placed on this Sequence Flow if this conditionExpression evaluates to `true`.

<table>
<thead>
<tr>
<th>isImmediate: boolean [0..1]</th>
</tr>
</thead>
</table>

An optional Boolean value specifying whether Activities or Choreography Activities not in the model containing the Sequence Flow can occur between the elements connected by the Sequence Flow. If the value is `true`, they MAY NOT occur. If the value is `false`, they MAY occur. Also see the `isClosed` attribute on Process, Choreography, and Collaboration.

When the attribute has no value, the default semantics depends on the kind of model containing Sequence Flow:

- For a `public` Processes and Choreographies no value has the same semantics as if the value were `false`.
- For an `executable` and `non-executable` (internal) Processes no value has the same semantics as if the value were `true`.
- For `executable` Processes, the attribute MUST NOT be `false`.

## Flow Node

The `FlowNode` element is used to provide a single element as the source and target `Sequence Flow` associations (see Figure 8-48, above) instead of the individual associations of the elements that can connect to `Sequence Flow` (see the section above). Only the Gateway, Activity, Choreography Activity, and Event elements can connect to `Sequence Flow` and thus, these elements are the only ones that are sub-classes of `FlowNode`.

Since Gateway, Activity, Choreography Activity, and Event have their own attributes, model associations, and inheritances; the `FlowNode` element does not inherit from any other BPMN element. Table 8-62 presents the additional model associations of the `FlowNode` element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>incoming: Sequence Flow</td>
<td>This attribute identifies the <em>incoming</em> Sequence Flow of the <code>FlowNode</code>.</td>
</tr>
<tr>
<td>outgoing: Sequence Flow</td>
<td>This attribute identifies the <em>outgoing</em> Sequence Flow of the <code>FlowNode</code>.</td>
</tr>
</tbody>
</table>

### 8.3.18. Common Package XML Schemas
Table 8-63 – CallableElement XML schema

```xml

        <xsd:element name="conditionExpression" type="tExpression" minOccurs="0" maxOccurs="1"/>
      </xsd:sequence>
      <xsd:attribute name="sourceRef" type="xsd:IDREF" use="required"/>
      <xsd:attribute name="targetRef" type="xsd:IDREF" use="required"/>
      <xsd:attribute name="isImmediate" type="xsd:boolean" default="true"/>
    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
```

### 8.4. Services

The Service package contains constructs necessary for modeling services, interfaces, and operations.
8.4.1. Interface

An Interface defines a set of operations that are implemented by Services.

The Interface inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to RootElement. Table 8-81 presents the additional attributes and model associations of the Interface:
### Table 8-81 – Interface attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td>operations: Operation</td>
<td>This attribute specifies operations that are defined as part of the Interface. An Interface has at least one Operation.</td>
</tr>
<tr>
<td>callableElements:</td>
<td>The CallableElements that use this Interface.</td>
</tr>
</tbody>
</table>

#### 8.4.2. EndPoint

The actual definition of the service address is out of scope of BPMN 2.0. The EndPoint element is an extension point and extends from RootElement. The EndPoint element may be extended with endpoint reference definitions introduced in other specifications (e.g. WS-Addressing).

Endpoints can be specified for Participants.

#### 8.4.3. Operation

An Operation defines Messages that are consumed and, optionally, produced when the Operation is called. It may also define zero or more errors that are returned when operation fails. The Operation inherits the attributes and model associations of BaseElement (see Table 8-5). Table 8-82 below presents the additional attributes and model associations of the Operation:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td>inMessageRef: Message</td>
<td>This attribute specifies the input Message of the Operation. An Operation has exactly one input Message.</td>
</tr>
<tr>
<td>outMessageRef: Message</td>
<td>This attribute specifies the output Message of the Operation. An Operation has at most one input Message.</td>
</tr>
<tr>
<td>errorRef: Error</td>
<td>This attribute specifies errors that the Operation may return. An Operation may refer to zero or more Error elements.</td>
</tr>
</tbody>
</table>

#### 8.4.4. Service Package XML Schemas

Table 8-83 – interface XML schema

  <xsd:complexContent>
    <xsd:extension base="tRootElement"/>
  </xsd:complexContent>
</xsd:complexType>
```
9. Collaboration

Note: The contents of this chapter are required for BPMN Choreography Modeling Conformance, BPMN Process Modeling Conformance, or for BPMN Complete Conformance. However, this chapter is not required for BPMN Process Execution Conformance or BPMN BPEL Process Execution Conformance. For more information about BPMN conformance types, see page 28.

The Collaboration package contains classes which are used for modeling Collaborations, which is a collection of Participants shown as Pools, their interactions as shown by Message Flow, and may include Processes within the Pools and/or Choreographies between the Pools (see Figure 9-1). When a Collaboration is defined it is contained in Definitions.

Figure 9-1 – Classes in the Collaboration package
The **Collaboration** element inherits the attributes and model associations of **BaseElement** (see Table 8-5) through its relationship to **RootElement**, and **InteractionSpecification** (see Table 8-48). Table 9-1 presents the additional attributes and model associations for the **Collaboration** element:

**Table 9-1 – Collaboration Attributes and Model Associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>Name is a text description of the Collaboration.</td>
</tr>
</tbody>
</table>
| choreographyRef: Choreography [0..1] | The choreographyRef model association defines a Choreography that is shown between the Pools of the Collaboration. A Choreography specifies a business contract (or the order in which messages will be exchanged) between interacting *Participants*. See page 327 for more details on Choreography.  
  The **participantAssociations** (see below) are used to map the *Participants* of the Choreography to the *Participants* of the Collaboration.  
  The **choreographyMessageFlowAssociations** (see below) are used to map the Message Flow of the Choreography to the Message Flow of the Collaboration. |
| conversationAssociations: ConversationAssociation [0..*] | This attribute provides the list of ConversationAssociations that are used to apply (reusable) Conversations to the Collaboration.  
  The **ConversationAssociations** is used to identify the Message Flow that are grouped by the referenced Conversation. This grouping can be done automatically through the **CorrelationKey** of the Conversation (matching the **CorrelationKey** to the Messages of the Message Flow) or done through user selection if a **CorrelationKey** has not been defined.  
  If the Conversation lists *Participants*, then the **participantAssociations** (see below) are used to map the *Participants* of the Conversation to the *Participants* of the Collaboration.  
  If the Conversation lists Message Flow, then the **MessageFlowAssociations** (see below) are used to map the Message Flow of the Conversation to the Message Flow of the Collaboration. |
| conversations: Conversation [0..*] | The conversation model aggregation relationship allows to have Conversations contained in a Collaboration, to group Message Flow of the Collaboration and associate *correlation* information, as is required for the definitional Collaboration of a Process model. Such a Conversation SHOULD only use Message Flow references to group the Message Flow of the enclosing Collaboration. |
| artifacts: Artifact [0..*]     | This attribute provides the list of Artifacts that are contained within the Collaboration. |
**participantAssociations:** ParticipantAssociations [0..*]

This attribute provides a list of mappings from the *Participants* of a referenced Choreography or Conversation to the *Participants* of the Collaboration. It can also provide mappings between *Participants* of a *definitional Collaboration* for a Process to *Participants* in *definitional Collaboration* of called Processes.

**messageFlowAssociations:** Message Flow Association [0..*]

This attribute provides a list of mappings for the Message Flow of the Collaboration to Message Flow of a referenced model. This applies for two (2) situations:

- When a Choreography is referenced by the Collaboration.
- When a Conversation is referenced by the Collaboration.

**IsClosed**: boolean = false

A Boolean value specifying whether Message Flow not modeled in the Collaboration can occur when the Collaboration is carried out. If the value is *true*, they MAY NOT occur. If the value is *false*, they MAY occur.

A set of Messages Flow of a particular Collaboration may belong to the same Conversation. A Conversation is a set of Message Flow that share a particular purpose—i.e., they all relate to the handling of a single order (see page 17 for more information about Conversations). Correlations are the mechanism that is used to identify the Messages and, consequently, the Message Flow that belong to the same Conversation. Correlations can be used to specify Conversations between Processes that follow a fairly simple Conversation pattern in the sense that:

- The conceptual data of the Conversation is well known and defined by the participating Processes. However this doesn’t mandate that underlying type systems are identical. It is sufficient that the data is known “conceptually” on a (potentially very high) business level.
- A Conversation takes place by means of simple Message exchange between Processes, no additional agreements must be considered.
- There exists send and receive Tasks accepting the conceptual data of the Conversation. (An Order send by a Task of a Process should be received by at least one Task of the participating Process)
- The correlation itself is defined in terms of correlation fields, which denote a subset of the conceptual data that should be used for the correlation. (For example, if the conceptual data comprises of an order than the correlation field might be denoted by the order ID).

In some applications it is useful to allow more Messages to be sent between Participants when a Collaboration is carried out than are contained the Collaboration model. This enables Participants to exchange other Messages as needed without changing the Collaboration. If the isClosed attribute of a Collaboration has a value of false or no value, then Participants MAY send Messages to each other without additional Message Flow in the Collaboration. If the isClosed attribute of a Collaboration has a value of true, then Participants MAY NOT send Messages to each other without additional Message Flow in the Collaboration. If a Collaboration contains a Choreography, then the value of the isClosed attribute MUST be the same in both. Restrictions on unmodeled messaging specified with isClosed apply only under the Collaboration containing the restriction. PartnerEntities and PartnerRoles of the Participants MAY send Messages to each other under other Choreographies, Collaborations, and Conversations.
9.1. Basic Collaboration Concepts

A **Collaboration** contains two (2) or more **Pools**, representing the **Participants** in the Collaboration. The Message exchange between the **Participants** is shown by a **Message Flow** that connects two (2) **Pools** (or the objects within the **Pools**). The **Messages** associated with the **Message Flow** may also be shown.

A **Pool** may be empty, a “black box,” or may show a **Process** within. **Choreographies** may be shown “in between” the **Pools** as they bisect the **Message Flow** between the **Pools**. All combinations of **Pools**, **Processes**, and a **Choreography** are allowed in a Collaboration.

9.1.1. Use of BPMN Common Elements

Some **BPMN** elements are common to both **Process** and **Choreography**, as well as **Collaboration**; they are used in these diagrams. The next few sections will describe the use of **Messages**, **Message Flow**, **Participants**, **Sequence Flow**, **Artifacts**, **Correlations**, **Expressions**, and **Services** in **Choreography**.

9.2. Pool and Participant

A **Pool** represents a **Participant** in a **Collaboration** or a **Choreography**. A **Participant** (see page 24) can be a specific **PartnerEntity** (e.g., a company) or can be a more general **PartnerRole** (e.g., a buyer, seller, or manufacturer). Graphically, a **Pool** is a container for partitioning a **Process** from other **Pools**. A **Pool** is not required to contain a **Process**, i.e., it can be a “black box”.

- A **Pool** is a square-cornered rectangle that MUST be drawn with a solid single line (see Figure 9-2).
- The label for the **Pool** MAY be placed in any location and direction within the **Pool**, but MUST be separated from the contents of the **Pool** by a single line.
- If the **Pool** is a black box (i.e., does not contain a **Process**), then the label for the **Pool** MAY be placed anywhere within the **Pool** without a single line separator.
- One, and only one, **Pool** in a diagram MAY be presented without a boundary. If there is more than one **Pool** in the diagram, then the remaining **Pools** MUST have a boundary.

The use of text, color, size, and lines for a **Pool** MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.

---

**Pool**

<table>
<thead>
<tr>
<th>Name</th>
</tr>
</thead>
</table>

**Figure 9-2 – A Pool**
To help with the clarity of the Diagram, a **Pool** extends the entire length of the Diagram, either horizontally or vertically. However, there is no specific restriction to the size and/or positioning of a **Pool**. Modelers and modeling tools can use **Pools** in a flexible manner in the interest of conserving the “real estate” of a Diagram on a screen or a printed page.

A **Pool** acts as the container for the **Sequence Flow** between **Activities** (of a contained **Process**). The **Sequence Flow** can cross the boundaries between **Lanes** of a **Pool** (see page 149 for more details on **Lanes**), but cannot cross the boundaries of a **Pool**. That is, a **Process** is fully contained within the **Pool**. The interaction between **Pools** is shown through **Message Flow**.

Another aspect of **Pools** is whether or not there is any **Activity** detailed within the **Pool**. Thus, a given **Pool** may be shown as a “**White Box**,” with all details (e.g., a **Process**) exposed, or as a “**Black Box**,” with all details hidden. No **Sequence Flow** is associated with a “**Black Box**” **Pool**, but **Message Flow** can attach to its boundaries (see Figure 9-3).

![Figure 9-3 – Message Flow connecting to the boundaries of two Pools](image)

For a “**White Box**” **Pool**, the **Activities** within are organized by **Sequence Flow**. **Message Flow** can cross the **Pool** boundary to attach to the appropriate **Activity** (see Figure 9-4).
Figure 9-4 – Message Flow connecting to Flow Objects within two Pools

A Collaboration contains at least two (2) Pools (i.e., Participants). However, the Activities that represent the work performed from the point of view of the modeler or the modeler’s organization may be considered “internal” Activities and are not required to be surrounded by the boundary of their Pool, while the other Pools in the Diagram MUST have their boundary (see Figure 9-5).

Figure 9-5 – Main (Internal) Pool without boundaries

BPMN specifies a marker for Pools: a multi-instance Marker May be displayed for a Pool (see Figure 9-6). The marker is used if the Participant defined for the Pool is a multi-instance Participant. See page 125 for more information on Participant multiplicity.

Proposal for:
Business Process Model and Notation (BPMN), v2.0
♦ The marker for a Pool that is a multi-instance MUST be a set of three vertical lines in parallel.
♦ The marker, if used, MUST be centered at the bottom of the shape.

![Supplier](image)

**Figure 9-6 – A Pool with a Multi-Instance Participant Marker**

### 9.2.1. Lanes

A Lane is a sub-partition within a Pool or a Process and will extend the entire length of the diagram, either vertically or horizontally. See page 316 for more information on Lanes.

### 9.3. Collaboration

Processes can be included in a Collaboration diagram. A Participant/Pool within the Collaboration can contain a Process (but they are not required). An example of this is shown in Figure 9-4 above. See page 324 for more details of how Processes are included with Collaborations.

### 9.4. Choreography within Collaboration

Choreographies can be included in a Collaboration diagram. A Collaboration specifies how the Participants and Message Flow in the Choreography are matched up with the Participants and Message Flow in the Collaboration. A Collaboration uses ParticipantAssociations and MessageFlowAssociations for this purpose.

To handle the Participants, the innerParticipant of a ParticipantAssociation refers to a Participant in the Choreography, while the outerParticipant refers to a Participant in the Collaboration containing the Choreography. This mapping matches the Participant Bands of the Choreography Activities in the Choreography to the Pools in the Collaboration. Thus, the names in the Participant Bands are not required (see Figure 9-7).
To handle Message Flow, the innerMessageFlow of a MessageFlowAssociation refers to a Message Flow in the Choreography, while the outerMessageFlow refers to a Message Flow in the Collaboration containing the Choreography. This mapping matches the Message Flow of the Choreography (which are not visible) to the Message Flow in the Collaboration (which are visible). This allows the Message Flow of the Collaboration to be “wired up” through the appropriate Choreography Activity in the Choreography (see Figure 9-7, above).

The ParticipantAssociations might be derived from the partnerEntities or partnerRoles of the Participants. For example, if a Choreography Activity has a Participant with the same partnerEntity as a Participant in the Collaboration containing the Choreography, then these two (2) Participants could be assumed to be the inner and outerParticipants of a ParticipantAssociation. Similarly, Message Flow that reference the same Message in a Call Choreography Activity and the Collaboration, could be automatically synchronized by a MessageFlowAssociation, if only one Message Flow has that Message.
Figure 9-8 – Choreography within Collaboration class diagram
9.5. Collaboration Package XML Schemas

Table 9-2 – Collaboration XML schema

```xml
<xsd:element name="collaboration" type="tCollaboration" substitutionGroup="rootElement"/>
<xsd:complexType name="tCollaboration">
    <xsd:complexContent>
        <xsd:extension base="tRootElement">
            <xsd:sequence>
                <xsd:element ref="participant" minOccurs="0" maxOccurs="unbounded"/>
                <xsd:element ref="messageFlow" minOccurs="0" maxOccurs="unbounded"/>
                <xsd:element ref="artifact" minOccurs="0" maxOccurs="unbounded"/>
                <xsd:element ref="conversation" minOccurs="0" maxOccurs="unbounded"/>
                <xsd:element name="conversationAssociation" minOccurs="0" maxOccurs="unbounded"/>
                <xsd:element ref="participantAssociation" minOccurs="0" maxOccurs="unbounded"/>
                <xsd:element name="MessageFlowAssociation" type="tMessageFlowAssociation" minOccurs="0" maxOccurs="unbounded"/>
            </xsd:sequence>
            <xsd:attribute name="name" type="xsd:string"/>
            <xsd:attribute name="isClosed" type="xsd:boolean" default="false"/>
            <xsd:attribute name="choreographyRef" type="xsd:QName" use="optional"/>
        </xsd:extension>
    </xsd:complexContent>
</xsd:complexType>
```
10. Process

Note: The content of this chapter is required for BPMN Process Modeling Conformance or for BPMN Complete Conformance. However, this chapter is not required for BPMN Process Choreography Conformance, BPMN Process Execution Conformance, or BPMN BPEL Process Execution Conformance. For more information about BPMN conformance types, see Page 28.

A Process describes a sequence or flow of Activities in an organization with the objective of carrying out work. In BPMN a Process is depicted as a graph of Flow Elements, which are a set of Activities, Events, Gateways, and Sequence Flow that define finite execution semantics (see Figure 10-1). Processes may be defined at any level from enterprise-wide Processes to Processes performed by a single person. Low-level Processes may be grouped together to achieve a common business goal.

![Figure 10-1 – An Example of a Process](image)

Note that BPMN uses the term Process specifically to mean a set of flow elements. It uses the terms Collaboration and Choreography when modeling the interaction between Processes.

The Process package contains classes which are used for modeling the flow of Activities, Events, and Gateways, and how they are sequenced within a Process (see Figure 10-2). When a Process is defined it is contained within Definitions.
A **Process** is a **CallableElement**, allowing it to be referenced and reused by other **Processes** via the **Call Activity** construct. In this capacity, a **Process** may reference a set of **Interfaces** that define its external behavior.

A **Process** is a reusable element and can be imported and used within other **Definitions**.
Figure 10-3 shows the details of the attributes and model associations of a Process.

![Diagram of Process Details class diagram]

Figure 10-3 – Process Details class diagram
The Process element inherits the attributes and model associations of CallableElement (see Table 8-30) and of FlowElementContainer (see Table 8-46). Table 10-1 presents the additional attributes and model associations of the Process element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>processType</strong>: ProcessType = none</td>
<td>The processType attribute provides additional information about the level of abstraction modeled by this Process. A public Process shows only those flow elements that are relevant to external consumers. Internal details are not modeled. These Processes are publicly visible and can be used within a Collaboration. Note that the public processType was named abstract in BPMN 1.2. The BPMN 1.2 processType private has been divided into two (2) types: An executable Process is a private Process that has been modeled for the purpose of being executed according to the semantics of Chapter 14 (see page 426). Of course, during the development cycle of the Process, there will be stages where the Process does not have enough detail to be &quot;executable.&quot; A non-executable Process is a private Process that has been modeled for the purpose of documenting Process behavior at a modeler-defined level of detail. Thus, information required for execution, such as formal condition expressions are typically not included in a non-executable Process. By default, the processType is “none”, meaning undefined.</td>
</tr>
<tr>
<td><strong>auditing</strong>: Auditing [0..1]</td>
<td>This attribute provides a hook for specifying audit related properties.</td>
</tr>
<tr>
<td><strong>monitoring</strong>: Monitoring [0..1]</td>
<td>This attribute provides a hook for specifying monitoring related properties.</td>
</tr>
<tr>
<td><strong>laneSets</strong>: LaneSet [0..*]</td>
<td>This attribute defines the list of LaneSets used in the Process.</td>
</tr>
<tr>
<td><strong>IsClosed</strong>: boolean = false</td>
<td>A Boolean value specifying whether interactions, such as sending and receiving Messages and Events, not modeled in the Process can occur when the Process is executed or performed. If the value is true, they MAY NOT occur. If the value is false, they MAY occur.</td>
</tr>
<tr>
<td><strong>supports</strong>: Process [0..*]</td>
<td>Modelers can declare that they intend all executions or performances of one Process to also be valid for another Process. This means they expect all the executions or performances of the first Processes to also follow the steps laid out in the second Process.</td>
</tr>
</tbody>
</table>
**Properties**: Property [0..*]

Modeler-defined properties MAY be added to a Process. These properties are “local” to the Process. All Tasks and Sub-Processes SHALL have access to these properties. The fully delineated name of these properties is “<process name>.<property name>” (e.g., “Add Customer.Customer Name”). If a Process is embedded within another Process, then the fully delineated name SHALL also be preceded by the parent Process name for as many parents there are until the top level Process.

**DefinitionalCollaborationRef**: Collaboration [0..1]

For Processes that interact with other Participants, a definitional Collaboration can be referenced by the Process. The definitional Collaboration specifies the Participants the Process interacts with, and more specifically, which individual service, Send or Receive Task, or Message Event, is connected to which Participant through Message Flow.

The definitional Collaboration need not be displayed.

Additionally, the definitional Collaboration can be used to include Conversation information within a Process.

In addition, a Process Instance has attributes whose values may be referenced by expressions (see Table 10-2). These values are only available when the Process is being executed.

### 10.1. Basic Process Concepts

#### 10.1.1. Types of BPMN Processes

Business Process modeling is used to communicate a wide variety of information to a wide variety of audiences. BPMN is designed to cover many types of modeling and allows the creation of end-to-end Business Processes. There are three basic types of BPMN Processes:

- **Private Non-executable** (internal) Business Processes
- **Private Executable** (internal) Business Processes
- **Public** Processes
Private (Internal) Business Processes

**Private Business Processes** are those internal to a specific organization. These Processes have been generally called workflow or BPM Processes (see Figure 10-4). Another synonym typically used in the Web services area is the *Orchestration* of services. There are two (2) types of private Processes: *executable* and *non-executable*. An executable Process is a Process that has been modeled for the purpose of being executed according to the semantics defined in Chapter 14. Of course, during the development cycle of the Process, there will be stages where the Process does not have enough detail to be “executable.” A non-executable Process is a private Process that has been modeled for the purpose of documenting Process behavior at a modeler-defined level of detail. Thus, information required for execution, such as formal condition expressions are typically not included in a non-executable Process.

If a swimlanes-like notation is used (e.g., a Collaboration, see below) then a private Business Process will be contained within a single Pool. The Process flow is therefore contained within the Pool and cannot cross the boundaries of the Pool. The flow of Messages can cross the Pool boundary to show the interactions that exist between separate private Business Processes.

![Figure 10-4 – Example of a private Business Process](image)

Public Processes

A public Process represents the interactions between a private Business Process and another Process or Participant (see Figure 10-5). Only those Activities that are used to communicate to the other Participant(s), plus the order of these Activities, are included in the public Process. All other “internal” Activities of the private Business Process are not shown in the public Process. Thus, the public Process shows to the outside world the Messages, and the order of these Messages, that are required to interact with that Business Process. Public Processes can be modeled separately or within a Collaboration to show the flow of Messages between the public Process Activities and other Participants. Note that the public type of Process was named “abstract” in BPMN 1.2.
10.1.2. Use of BPMN Common Elements

Some BPMN elements are common to both Process and Choreography, as well as Collaboration; they are used in both types of diagrams. The next few sections will describe the use of Messages, Message Flow, Participants, Sequence Flow, Artifacts, Correlations, Expressions, and Services in Choreography.

The key graphical elements of Gateways and Events are also common to both Choreography and Process. Since their usage has a large impact, they are described in major sections of this chapter (see page 239 for Events and page 295 for Gateways).

10.2. Activities

An Activity is work that is performed within a Business Process. An Activity can be atomic or non-atomic (compound). The types of Activities that are a part of a Process are: Task, Sub-Process, and Call Activity, which allows the inclusion of re-usable Tasks and Processes in the diagram. However, a Process is not a specific graphical object. Instead, it is a set of graphical objects. The following sections will focus on the graphical objects Sub-Process and Task.

Activities represent points in a Process flow where work is performed. They are the executable elements of a BPMN Process.

The Activity class is an abstract element, sub-classing from FlowElement (as shown in Figure 10-6).

Concrete sub-classes of Activity specify additional semantics above and beyond that defined for the generic Activity.
Figure 10-6 – Activity class diagram

The Activity class is the abstract super class for all concrete Activity types.

The Activity element inherits the attributes and model associations of FlowElement (see Table 8-45). Table 10-3 presents the additional attributes and model associations of the Activity element:

Table 10-3 – Activity attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isForCompensation: boolean = false</td>
<td>A flag that identifies whether this activity is intended for the purposes of compensation. If false, then this activity executes as a result of normal execution flow. If true, this activity is only activated when a Compensation Event is detected and initiated under Compensation Event visibility scope (see page 288 for more information on scopes).</td>
</tr>
<tr>
<td>loopCharacteristics: LoopCharacteristics [0..1]</td>
<td>An activity may be performed once or may be repeated. If repeated, the activity MUST have loopCharacteristics which define the repetition criteria (if the processType attribute of the Process is set to executable).</td>
</tr>
<tr>
<td>resource</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>resources:</code> ActivityResource [0..*]</td>
<td>Defines the resource that will perform or will be responsible for the activity. The resource, e.g. a performer, can be specified in the form of a specific individual, a group, an organization role or position, or an organization.</td>
</tr>
<tr>
<td><code>default:</code> SequenceFlow [0..1]</td>
<td>The Sequence Flow that will receive a Token when none of the conditionExpressions on other outgoing Sequence Flow evaluate to true. The default Sequence Flow should not have a conditionExpression. Any such Expression SHALL be ignored.</td>
</tr>
<tr>
<td><code>properties:</code> Property [0..*]</td>
<td>Modeler-defined properties MAY be added to an Activity. These properties are “local” to the Activity. The fully delineated name of these properties is “&lt;activity name&gt;.&lt;property name&gt;” (e.g., “Add Customer.Customer Name”).</td>
</tr>
<tr>
<td><code>boundaryEventRefs:</code> BoundaryEvent [0..*]</td>
<td>This references the Intermediate Events that are attached to the boundary of the Activity.</td>
</tr>
<tr>
<td><code>dataInputAssociations:</code> DataInputAssociation [0..*]</td>
<td>An optional reference to the DataInputAssociations. A DataInputAssociation defines how the DataInput of the Activity’s InputOutputSpecification will be populated.</td>
</tr>
<tr>
<td><code>dataOutputAssociations:</code> DataOutputAssociation [0..*]</td>
<td>An optional reference to the DataOutputAssociations.</td>
</tr>
<tr>
<td><code>startQuantity:</code> integer = 1</td>
<td>The default value is 1. The value MUST NOT be less than 1. This attribute defines the number of tokens that must arrive before the Activity can begin. Note that any value for the attribute that is greater than 1 is an advanced type of modeling and should be used with caution.</td>
</tr>
<tr>
<td><code>completionQuantity:</code> integer = 1</td>
<td>The default value is 1. The value MUST NOT be less than 1. This attribute defines the number of tokens that must be generated from the Activity. This number of tokens will be sent done any outgoing Sequence Flow (assuming any Sequence Flow Conditions are satisfied). Note that any value for the attribute that is greater than 1 is an advanced type of modeling and should be used with caution.</td>
</tr>
</tbody>
</table>

In addition, an Activity instance has attributes whose values may be referenced by expressions. These values are only available when the Activity is being executed.
Table 8-57 presents the Instance attributes of the Activity element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>state: string = none (none</td>
<td>ready</td>
</tr>
</tbody>
</table>

Sequence Flow Connections

See Section “Sequence Flow Connections Rules” on page 64 for the entire set of objects and how they may be source or targets of Sequence Flow.

✦ An Activity MAY be a target for Sequence Flow; it can have multiple incoming Sequence Flow. Incoming Sequence Flow MAY be from an alternative path and/or parallel paths.

✦ If the Activity does not have an incoming Sequence Flow, and there is no Start Event for the Process, then the Activity MUST be instantiated when the Process is instantiated.

✦ There are two (2) exceptions to this: Compensation Activities and Event Sub-Processes.

Note – If the Activity has multiple incoming Sequence Flow, then this is considered uncontrolled flow. This means that when a token arrives from one of the Paths, the Activity will be instantiated. It will not wait for the arrival of tokens from the other paths. If another token arrives from the same path or another path, then a separate instance of the Activity will be created. If the flow needs to be controlled, then the flow should converge on a Gateway that precedes the Activities (see 295 for more information on Gateways).

✦ An Activity MAY be a source for Sequence Flow; it can have multiple outgoing Sequence Flow. If there are multiple outgoing Sequence Flow, then this means that a separate parallel path is being created for each Sequence Flow (i.e., tokens will be generated for each outgoing Sequence Flow from the Activity).

✦ If the Activity does not have an outgoing Sequence Flow, and there is no End Event for the Process, then the Activity marks the end of one or more paths in the Process. When the Activity ends and there are no other parallel paths active, then the Process MUST be completed.

✦ There are two (2) exceptions to this: Compensation Activities and Event Sub-Processes.
Message Flow Connections

See Section “Message Flow Connection Rules” on page 65 for the entire set of objects and how they may be source or targets of Message Flow.

Note – All Message Flow must connect two separate Pools. They can connect to the Pool boundary or to Flow Objects within the Pool boundary. They cannot connect two objects within the same Pool.

- An Activity MAY be the target for Message Flow; it can have zero or more incoming Message Flow.
- A Activity MAY be a source for Message Flow; it can have zero or more outgoing Message Flow.

10.2.1. Resource Assignment

The following sections define how required Resources can be defined for an Activity. Figure 10-7 displays the class diagram for the BPMN elements used for Resource assignment.

![Class Diagram for Assigning Resources](Figure 10-7)

**Figure 10-7 – The class diagram for assigning Resources**

Activity Resource
The **ActivityResource** element inherits the attributes and model associations of **BaseElement** (see Table 8-5). Table 10-5 presents the additional model associations of the **ActivityResource** element:

**Table 10-5 – ActivityResource model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceRef: Resource</td>
<td>The <strong>Resource</strong> that will be used by the <strong>ActivityResource</strong>.</td>
</tr>
<tr>
<td>resourceAssignmentExpression: ResourceAssignmentExpression [0..1]</td>
<td>This defines the <strong>Expression</strong> used for the <strong>Resource</strong> assignment (see below).</td>
</tr>
<tr>
<td>resourceParameterBindings: ResourceParameterBindings [0..*]</td>
<td>This defines the <strong>Parameter</strong> bindings used for the <strong>Resource</strong> assignment (see below).</td>
</tr>
</tbody>
</table>

**Expression Assignment**

**Resources** can be assigned to an **Activity** using **Expressions**. These **Expressions** must return **Resource** entity related data types, like Users or Groups. Different **Expressions** can return multiple **Resources**. All of them are assigned to the respective subclass of the **ActivityResource** element, for example as potential owners. The semantics is defined by the subclass.

The **ResourceAssignmentExpression** element inherits the attributes and model associations of **BaseElement** (see Table 8-5). Table 10-6 presents the additional model associations of the **ResourceAssignmentExpression** element:

**Table 10-6 – ResourceAssignmentExpression model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression: Expression</td>
<td>The element <strong>ResourceAssignmentExpression</strong> must contain an expression which is used at runtime to assign resource(s) to a <strong>ActivityResource</strong> element.</td>
</tr>
</tbody>
</table>
Parameterized Resource Assignment

Resources support query parameters which are passed to the Resource query at runtime. Parameters may refer to Task instance data using expressions. During Resource query execution, an infrastructure may decide which of the Parameters defined by the Resource are used. It may use zero (0) or more of the Parameters specified. It may also override certain Parameters with values defined during Resource deployment. The deployment mechanism for Tasks and Resources is out of scope for this specification. Resource queries are evaluated to determine the set of Resources, e.g. people, assigned to the Activity. Failed Resource queries are treated like Resource queries that return an empty result set. Resource queries return one Resource or a set of Resources.

The ResourceParameterBinding element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 10-7 presents the additional model associations of the ResourceParameterBinding element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameterRef: ResourceParameter [1]</td>
<td>Reference to the parameter defined by the Resource</td>
</tr>
<tr>
<td>expression: Expression</td>
<td>The Expression that evaluates the value used to bind the ResourceParameter</td>
</tr>
</tbody>
</table>

**Table 10-7 – ResourceParameterBinding model associations**

10.2.2. Performer

The Performer class defines the resource that will perform or will be responsible for an Activity. The performer can be specified in the form of a specific individual, a group, an organization role or position, or an organization.

The Performer element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to ActivityResource, but does not have any additional attributes or model associations.

10.2.3. Tasks

A Task is an atomic Activity within a Process flow. A Task is used when the work in the Process cannot be broken down to a finer level of detail. Generally, an end-user and/or applications are used to perform the Task when it is executed.

A Task object shares the same shape as the Sub-Process, which is a rectangle that has rounded corners (see Figure 10-8):}

- A Task is a rounded corner rectangle that MUST be drawn with a single thin line.
- The use of text, color, size, and lines for a Task MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.
A boundary drawn with a thick line SHALL be reserved for **Call Activity** (Global Tasks) (see page 196).

A boundary drawn with a dotted line SHALL be reserved for **Event Sub-Processes** (see page 188) and thus are not allowed for **Tasks**.

A boundary drawn with a double line SHALL be reserved for **Transaction Sub-Processes** (see page 190) and thus are not allowed for **Tasks**.

**Figure 10-8 – A Task object**

**BPMN** specifies three types of markers for **Task**: a **Loop** marker or a **Multi-Instance** marker and a **Compensation** marker. A **Task** may have one or two of these markers (see **Figure 10-9**).

- The marker for a **Task** that is a standard **loop** MUST be a small line with an arrowhead that curls back upon itself. See page 200 for more information on **loop Activities**.
- The **loop** Marker MAY be used in combination with the **compensation** marker.
- The marker for a **Task** that is a multi-instance MUST be a set of three vertical lines. See page 201 for more information on **multi-instance Activities**.
- If the multi-instance instances are set to be performed in sequence rather than parallel, then the marker will be rotated 90 degrees (see **Figure 10-45**, below).
- The multi-instance marker MAY be used in combination with the compensation marker.
- The marker for a **Task** that is used for compensation MUST be a pair of left facing triangles (like a tape player “rewind” button). See page 314 for more information on compensation.
- The Compensation Marker MAY be used in combination with the loop marker or the multi-instance marker.
- All the markers that are present MUST be grouped and the whole group centered at the bottom of the shape.

**Figure 10-9 – Task markers**
Figure 10-10 displays the class diagram for the Task element.

The Task inherits the attributes and model associations of Activity (see Table 10-3). There are no further attributes or model associations of the Task.

Types of Tasks

There are different types of Tasks identified within BPMN to separate the types of inherent behavior that Tasks might represent. The list of Task types may be extended along with any corresponding indicators. A Task which is not further specified is called Abstract Task (this was referred to as the None Task in BPMN 1.2). The notation of the Abstract Task is shown in Figure 10-8.

Service Task

A Service Task is a Task that uses some sort of service, which could be a Web service or an automated application.

A Service Task object shares the same shape as the Task, which is a rectangle that has rounded corners. However, there is a graphical marker in the upper left corner of the shape that indicates that the Task is a Service Task (see Figure 10-11).

- A Service Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes a marker that distinguishes the shape from other Task types (as shown in Figure 10-11).
The Service Task inherits the attributes and model associations of Activity (see Table 10-3). In addition the following constraints are introduced. The Service Task has exactly one InputSet and at most one OutputSet. The Service Task inputs map to the parts of the input Message, that is the attributes inside of the Message (see section on Operation below). For a WSDL message, this would be expressed as message parts. The Service Task outputs map to the parts of the output Message, which are the attributes inside of the Message.

The actual Participant whose service is used can be identified by connecting the Service Task to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10-1.
Figure 10-12 – The Service Task class diagram

The Service Task inherits the attributes and model associations of Activity (see Table 10-3) presents additional the model associations of the Service Task:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>implementation: Implementation = Web Service (Web Service</td>
<td>This attribute specifies the technology that will be used to send and receive the Messages. A Web service is the default technology.</td>
</tr>
<tr>
<td>operationRef: Operation [0..1]</td>
<td>This attribute specifies the operation that is invoked by the Service Task.</td>
</tr>
</tbody>
</table>
Send Task

A Send Task is a simple Task that is designed to send a Message to an external Participant (relative to the Process). Once the Message has been sent, the Task is completed.

The actual Participant which the Message is sent can be identified by connecting the Send Task to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10-1.

A Send Task object shares the same shape as the Task, which is a rectangle that has rounded corners. However, there is a filled envelope marker (the same marker as a throw Message Event) in the upper left corner of the shape that indicates that the Task is a Send Task (see Figure 10-11).

- A Send Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes a filled envelope marker that distinguishes the shape from other Task types (as shown in Figure 10-13).

![Send Task Object](image-url)
Figure 10-8 – The Send Task and Receive Task class diagram
The Send Task inherits the attributes and model associations of Activity (see Table 10-3) presents the additional model associations of the Receive Task:

**Table 10-9 – Send Task model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageRef: Message [0..1]</td>
<td>A Message for the messageRef attribute MAY be entered. This indicates that the Message will be sent by the Task. The Message in this context is equivalent to an out-only message pattern (Web service). One or more corresponding outgoing Message Flow MAY be shown on the diagram. However, the display of the Message Flow is not required. The Message is applied to all outgoing Message Flow and the Message will be sent down all outgoing Message Flow at the completion of a single instance of the Task.</td>
</tr>
<tr>
<td>operationRef: Operation</td>
<td>This attribute specifies the operation that is invoked by the Service Task.</td>
</tr>
<tr>
<td>implementation:</td>
<td>This attribute specifies the technology that will be used to send and receive the Messages. A Web service is the default technology.</td>
</tr>
<tr>
<td>[Web Service</td>
<td>Other</td>
</tr>
</tbody>
</table>

**Receive Task**

A Receive Task is a simple Task that is designed to wait for a Message to arrive from an external Participant (relative to the Process). Once the Message has been received, the Task is completed.

The actual Participant from which the Message is received can be identified by connecting the Receive Task to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10-1.

A Receive Task is often used to start a Process. In a sense, the Process is bootstrapped by the receipt of the Message. In order for the Task to Instantiate the Process it must meet one of the following conditions:

- The Process does not have a Start Event and the Receive Task has no incoming Sequence Flow.
- The incoming Sequence Flow for the Receive Task has a source of a Start Event.
  - Note that no other incoming Sequence Flow are allowed for that Receive Task (in particular, a loop connection from a downstream object).

A Receive Task object shares the same shape as the Task, which is a rectangle that has rounded corners. However, there is an unfilled envelope marker (the same marker as a catch Message Event) in the upper left corner of the shape that indicates that the Task is a Receive Task (see Figure 10-14).

- A Receive Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes an unfilled envelope marker that distinguishes the shape from other Task types (as shown in Figure 10-14).
The Receive Task inherits the attributes and model associations of Activity (see Table 10-3). Table 10-10 presents the additional attributes and model associations of the Receive Task:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageRef: Message [0..1]</td>
<td>A Message for the messageRef attribute MAY be entered. This indicates that the Message will be received by the Task. The Message in this context is equivalent to an in-only message pattern (Web service). One or more corresponding incoming Message Flow MAY be shown on the diagram. However, the display of the Message Flow is not required. The Message is applied to all incoming Message Flow, but can arrive for only one of the incoming Message Flow for a single instance of the Task.</td>
</tr>
<tr>
<td>Instantiate: boolean = False</td>
<td>Receive Tasks can be defined as the instantiation mechanism for the Process with the Instantiate attribute. This attribute MAY be set to true if the Task is the first activity after the Start Event or a starting Task if there is no Start Event (i.e., there are no incoming Sequence Flow). Multiple Tasks MAY have this attribute set to True.</td>
</tr>
<tr>
<td>operationRef: Operation</td>
<td>This attribute specifies the operation that is invoked by the Service Task.</td>
</tr>
<tr>
<td>implementation: Implementation = Web Service {Web Service</td>
<td>Other</td>
</tr>
</tbody>
</table>

User Task

A User Task is a typical “workflow” Task where a human performer performs the Task with the assistance of a software application and is scheduled through a task list manager of some sort.

- A User Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes a human figure marker that distinguishes the shape from other Task types (as shown in Figure 10-15).
Manual Task

A Manual Task is a Task that is expected to be performed without the aid of any business process execution engine or any application. An example of this could be a telephone technician installing a telephone at a customer location.

- A Manual Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes a hand figure marker that distinguishes the shape from other Task types (as shown in Figure 10-16).

Business Rule

A Business Rule Task provides a mechanism for the Process to provide input to a Business Rules Engine and to get the output of calculations that the Business Rules Engine might provide. The InputOutputSpecification of the Task (see page 118) will allow the Process to send data to and receive data from the Business Rules Engine.

A Business Rule Task object shares the same shape as the Task, which is a rectangle that has rounded corners. However, there is a graphical marker in the upper left corner of the shape that indicates that the Task is a Business Rule Task (see Figure 10-11).

- A Business Rule Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes a marker that distinguishes the shape from other Task types (as shown in Figure 10-17).
The Business Rule Task inherits the attributes and model associations of Activity (see Table 10-3). Table 10-11 presents the additional attributes of the Business Rule Task:

### Table 10-11 – Business Rule Task attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>

<tbody>
<tr>
<td>Implementation: BusinessRuleTaskImplementation = Other</td>
<td>This attribute specifies the technology that will be used to implement the Business Rule Task</td>
</tr>
<tr>
<td>*(BusinessRuleWebService</td>
<td>WebService</td>
</tr>
</tbody>
</table>

Script Task

A Script Task is executed by a business process engine. The modeler or implementer defines a script in a language that the engine can interpret. When the Task is ready to start, the engine will execute the script. When the script is completed, the Task will also be completed.

A Script Task object shares the same shape as the Task, which is a rectangle that has rounded corners. However, there is a graphical marker in the upper left corner of the shape that indicates that the Task is a Script Task (see Figure 10-11).

- A Script Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes a marker that distinguishes the shape from other Task types (as shown in Figure 10-18).

### Figure 10-18 – A Script Task Object

The Script Task inherits the attributes and model associations of Activity (see Table 10-3). Table 10-12 presents the additional attributes of the Script Task:
### Table 10-12 – Script Task attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>scriptLanguage</code></td>
<td>Defines the script language. The script language MUST be provided if a script is provided.</td>
</tr>
<tr>
<td><code>script</code></td>
<td>The modeler MAY include a script that can be run when the Task is performed. If a script is not included, then the Task will act equivalent to a TaskType of None.</td>
</tr>
</tbody>
</table>

### 10.2.4. Human Interactions

#### Tasks with Human involvement

In many business workflows, human involvement is required to complete certain Tasks specified in the workflow model. BPMN specifies two different types of Tasks with human involvement, the Manual Task and the User Task.

A User Task is executed by and managed by a business process runtime. Attributes concerning the human involvement, like people assignments and UI rendering can be specified in great detail. A Manual Task is neither executed by nor managed by a business process runtime.

#### Notation

Both, the Manual Task and User Task share the same shape, which is a rectangle that has rounded corners. Manual Tasks and User Tasks have a Icons to indicate the human involvement required to complete the Task (see Figure 10-15 and Figure 10-16, above)

#### Manual Task

A Manual Task is a Task that is not managed by any business process engine. It can be considered as an unmanaged Task, unmanaged in the sense of that the business process engine doesn’t track the start and completion of such a Task. An example of this could be a paper based instruction for a telephone technician to install a telephone at a customer location.
The User Task inherits the attributes and model associations of Activity (see Table 10-3) but does not have any additional attributes or model associations.

**User Task**

A User Task is a typical “workflow” Task where a human performer performs the Task with the assistance of a software application, and where the Task is scheduled through a Task list manager of some sort.
The User Task can be implemented using different technologies, specified by the UserTaskImplementation.
The **User Task** inherits the attributes and model associations of **Activity** (see Table 10-3), Table 10-13 presents the additional attributes and model associations of the **User Task**:

**Table 10-13 – User Task attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementation: UserTaskImplementation = Other</td>
<td>This attribute specifies the technology that will be used to implement the User Task</td>
</tr>
<tr>
<td>renderings: Rendering [0..*]</td>
<td>This attribute acts as a hook which allows BPMN adopters to specify task rendering attributes by using the BPMN Extension mechanism</td>
</tr>
</tbody>
</table>

The **User Task** inherits the **Instance** attributes of **Activity** (see Table 8-57), Table 10-14 presents the **Instance** attributes of the **User Task** element:

**Table 10-14 – User Task **Instance** attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>actualOwner: string</td>
<td>Returns the “user” who picked/claimed the User task and became the actual owner of it. The value is a literal representing the user’s id, email address etc.</td>
</tr>
<tr>
<td>taskPriority: integer</td>
<td>Returns the priority of the User Task</td>
</tr>
</tbody>
</table>

**Rendering of User Tasks**

**BPMN User Tasks** need to be rendered on user interfaces like forms clients, portlets, etc. The Rendering element provides an extensible mechanism for specifying UI renderings for **User Tasks** (Task UI). The element is optional. One or more rendering methods may be provided in a **Task** definition. A **User Task** can be deployed on any compliant implementation, irrespective of the fact whether the implementation supports specified rendering methods or not. The Rendering element is the extension point for renderings. Things like language considerations are opaque for the Rendering element because the rendering applications typically provide Multilanguage support. Where this is not the case, providers of certain rendering types may decide to extend the rendering type in order to provide language information for a given rendering. The content of the rendering element is not defined by this specification.

**Human Performers**

People can be assigned to **Activities** in various roles (called “generic human roles” in WS-HumanTask). **BPMN 1.2** traditionally only has the **Performer** role. In addition to supporting the Performer role, **BPMN 2.0**
defines a specific HumanPerformer element allowing specifying more specific human roles as specialization of HumanPerformer, such as PotentialOwner.

**Figure 10-21 – HumanPerformer class diagram**

The HumanPerformer element inherits the attributes and model associations of ActivityResource (see Table 10-5), through its relationship to Performer, but does not have any additional attributes or model associations.

**Potential Owners**

Potential owners of an User Task are persons who can claim and work on it. A potential owner becomes the actual owner of a Task, usually by explicitly claiming it.
XML Schema for Human Interactions

Examples

Consider the following sample procurement Process from the Buyer perspective

![Procurement Process Example](image)

Figure 10-22 – Procurement Process Example

The Process comprises of two User Tasks
• **Approve Order**: After the quotation handling, the order needs to be approved by some regional manager to continue with the order and shipment handling

• **Review Order**: Once the order has been shipped to the Buyer, the order and shipment documents will be reviewed again by someone.

The details of the Resource and resource assignments are not shown in the BPMN above. See below XML sample of the “Buyer” Process for the Resource usage and resource assignments for potential owners.

**Table 10-19 – XML serialization of Buyer process**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<definitions id="Definition"
  targetNamespace="http://www.example.org/UserTaskExample"

    <conditionExpression>Was the Order Approved?</conditionExpression>
  </sequenceFlow>
</definitions>
```
10.2.5. Sub-Processes

A Sub-Process is an Activity whose internal details have been modeled using Activities, Gateways, Events, and Sequence Flow. A Sub-Process is a graphical object within a Process, but it also can be “opened up” to show a lower-level Process. Sub-Processes define a contextual scope that can be used for attribute visibility, transactional scope, for the handling of exceptions (see page 283 for more details), of Events, or for compensation (see page 314 for more details).

There are different types of Sub-Processes, which will be described in the next five (5) sections.

Embedded Sub-Process (Sub-Process)

A Sub-Process object shares the same shape as the Task object, which is a rounded rectangle.
A Sub-Process is a rounded corner rectangle that MUST be drawn with a single thin line.

- The use of text, color, size, and lines for a Sub-Process MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63 with the exception that:
  - A boundary drawn with a thick line SHALL be reserved for Call Activity (Sub-Processes) (see page 196).
  - A boundary drawn with a dotted line SHALL be reserved for Event Sub-Processes (see page 188).
  - A boundary drawn with a double line SHALL be reserved for Transaction Sub-Processes (see page 188).

The Sub-Process can be in a collapsed view that hides its details (see Figure 10-23) or a Sub-Process can be in an expanded view that shows its details within the view of the Process in which it is contained (see Figure 10-24). In the collapsed form, the Sub-Process object uses a marker to distinguish it as a Sub-Process, rather than a Task.

- The Sub-Process marker MUST be a small square with a plus sign (+) inside. The square MUST be positioned at the bottom center of the shape.

![Collapsed Sub-Process](image)

**Figure 10-23 – A Sub-Process object (collapsed)**

![Expanded Sub-Process](image)

**Figure 10-24 – A Sub-Process object (expanded)**

They are used to create a context for exception handling that applies to a group of Activities (see page 283 for more details). Compensations can be handled similarly (see page 314 for more details).

Expanded Sub-Processes may be used as a mechanism for showing a group of parallel Activities in a less-cluttered, more compact way. In Figure 10-25, Activities “C” and “D” are enclosed in an unlabeled expanded Sub-Process. These two Activities will be performed in parallel. Notice that the expanded Sub-Process does not include a Start Event or an End Event and the Sequence Flow to/from these
Events. This usage of expanded Sub-Processes for “parallel boxes” is the motivation for having Start and End Events being optional objects.

Figure 10-25 – Expanded Sub-Process used as a “Parallel Box”

BPMN specifies five (5) types of standard markers for Sub-Processes. The (Collapsed) Sub-Process marker, seen in Figure 10-23, can be combined with four (4) other markers: a loop marker or a multi-instance marker, a Compensation marker, and an Ad-Hoc marker. A collapsed Sub-Process may have one to three of these other markers, in all combinations except that loop and multi-instance cannot be shown at the same time (see Figure 10-26).

- The marker for a Sub-Process that loops MUST be a small line with an arrowhead that curls back upon itself.
- The loop marker MAY be used in combination with any of the other markers except the multi-instance marker.
- The marker for a Sub-Process that has Multiple Instances MUST be a set of three vertical lines in parallel.
- The multi-instance marker MAY be used in combination with any of the other markers except the loop marker.
- The marker for an ad-hoc Sub-Process MUST be a “tilde” symbol.
- The ad-hoc marker MAY be used in combination with any of the other markers.
- The marker for a Sub-Process that is used for compensation MUST be a pair of left facing triangles (like a tape player “rewind” button).
- The Compensation marker MAY be used in combination with any of the other markers.
- All the markers that are present MUST be grouped and the whole group centered at the bottom of the Sub-Process.
The Sub-Process now corresponds to the Embedded Sub-Process of BPMN 1.2. The Reusable Sub-Process of BPMN 1.2 corresponds to the Call Activity (calling a Process – see page 196). Figure 10-27 shows the class diagram related to Sub-Processes.

Figure 10-27 – The Sub-Process class diagram
The Sub-Process element inherits the attributes and model associations of Activity (see Table 10-3) and of FlowElementContainer (see Table 8-46). Table 10-3 presents the additional attributes of the Sub-Process element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>triggeredByEvent</td>
<td>A flag that identifies whether this Sub-Process is an Event Sub-Process. If false, then this Sub-Process is a normal Sub-Process. If true, the this Sub-Process is an Event Sub-Process and is subject to additional constraints (see page 188).</td>
</tr>
</tbody>
</table>

Reusable Sub-Process (Call Activity)

The reusable Sub-Process of BPMN 1.2 corresponds to the Call Activity that calls a pre-defined Process. See details of a Call Activity on page 196.

Event Sub-Process

An Event Sub-Process is a specialized Sub-Process that used within a Process (or Sub-Process). A Sub-Process is defined as an Event Sub-Process when its triggeredByEvent attribute is set to true.

An Event Sub-Process is not part of the normal flow of its parent Process—there are no incoming or outgoing Sequence Flow.

- An Event Sub-Process MUST NOT have any incoming or outgoing Sequence Flow.

An Event Sub-Process may or may not occur while the parent Process is active, but it is possible that it will occur many times. Unlike a standard Sub-Process, which uses the flow of the parent Process as a trigger, an Event Sub-Process has a Start Event with a trigger. Each time the Start Event is triggered while the parent Process is active, then the Event Sub-Process will start.

- The Start Event of an Event Sub-Process MUST have a defined trigger.
  - The Start Event trigger (EventDefinition) MUST be from the following types: Message, Error, Escalation, Compensation, Conditional, Signal, and Multiple (see page 266 for more details).
  - An Event Sub-Process MUST have one and only one Start Event.

An Event Sub-Process object shares the same basic shape as the Sub-Process object, which is a rounded rectangle.

- An Event Sub-Process is a rounded corner rectangle that MUST be drawn with a single thin dotted line (see Figure 10-28 and Figure 10-29).
  - The use of text, color, size, and lines for a Sub-Process MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63 with the exception that:
• If the Event Sub-Process is collapsed, then its Start Event will be used as a marker in the upper left corner of the shape (see Figure 10-28).

![Collapsed Event Sub-Process](image1)

**Figure 10-28 – An Event Sub-Process object (Collapsed)**

![Expanded Event Sub-Process](image2)

**Figure 10-29 – An Event Sub-Process object (expanded)**

There are two (2) possible consequences to the parent Process when an Event Sub-Process is triggered: 1) the parent Process can be interrupted, and 2) the parent Process can continue its work (not interrupted). This is determined by the type of Start Event that is used. See page 247 for the list of interrupting and non-interrupting Event Sub-Process Start Events.

![Figure 10-30](image3)

**Figure 10-30** provides an example of a Sub-Process that includes three (3) Event Sub-Processes. The first Event Sub-Process is triggered by a Message, does not interrupt the Sub-Process, and can occur multiple times. The second Event Sub-Process is used for compensation and will only occur after the Sub-Process has completed. The third Event Sub-Process handles errors that occur while the Sub-Process is active and will stop (interrupt) the Sub-Process if triggered.
Figure 10-30 – An example that includes Event Sub-Processes

Transaction

A Transaction is a specialized type of Sub-Process which will have a special behavior that is controlled through a transaction protocol (such as WS-Transaction). The boundary of the Sub-Process will be double-lined to indicate that it is a Transaction (see Figure 10-31).

- A Transaction Sub-Process is a rounded corner rectangle that MUST be drawn with a double thin line.
- The use of text, color, size, and lines for a transaction Sub-Process MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.
Figure 10-31 – A Transaction Sub-Process
The **Transaction Sub-Process** element inherits the attributes and model associations of **Activities** (see Table 10-3) through its relationship to **Sub-Process**. Table 10-21 presents the additional attributes and model associations of the **Transaction Sub-Process**:

**Table 10-21 – Transaction Sub-Process attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>protocol: string [0..1]</td>
<td>The elements that make up the internal Sub-Process flow. This association is only applicable when the XSD Interchange is used. In the case of the XMI interchange, this association is inherited from the FlowElementsContainer class.</td>
</tr>
<tr>
<td>method: TransactionMethod = compensate</td>
<td>TransactionMethod is an attribute that defines the technique that will be used to undo a Transaction that has been cancelled. The default is <code>compensate</code>, but the attribute MAY be set to <code>store</code> or <code>IMAGE</code>.</td>
</tr>
</tbody>
</table>

There are three basic outcomes of a **Transaction**:

- **Successful completion**: this will be shown as a normal Sequence Flow that leaves the **Transaction Sub-Process**.

- **Failed completion (Cancel)**: When a **Transaction** is cancelled, the Activities inside the **Transaction** will be subjected to the cancellation actions, which could include rolling back the **Process** and compensation (see page 314 for more information on compensation) for specific Activities. Note that other mechanisms for interrupting a **Transaction Sub-Process** will not cause compensation (e.g., Error, Timer, and anything for a non-Transaction Activity). A **Cancel Intermediate Event**, attached to the boundary of the Activity, will direct the flow after the **Transaction** has been rolled back and all compensation has been completed. The **Cancel Intermediate Event** can only be used when attached to the boundary of a **Transaction Sub-Process**. It cannot be used in any normal flow and cannot be attached to a non-Transaction **Sub-Process**. There are two mechanisms that can signal the cancellation of a **Transaction**:
  - A **Cancel End Event** is reached within the **transaction** **Sub-Process**. A **Cancel End Event** can only be used within a **transaction Sub-Process**.
  - A **cancel** **Message** can be received via the transaction protocol that is supporting the execution of the **Transaction Sub-Process**.

- **Hazard**: This means that something went terribly wrong and that a normal success or cancel is not possible. **Error Intermediate Events** are used to show **Hazards**. When a **Hazard** happens, the **Activity** is interrupted (without compensation) and the flow will continue from the **Error Intermediate Event**.

The behavior at the end of a successful **Transaction Sub-Process** is slightly different than that of a normal **Sub-Process**. When each path of the **Transaction Sub-Process** reaches a non-**Cancel End Event**(s), the flow does not immediately move back up to the higher-level **parent Process**, as does a normal **Sub-Process**. First, the transaction protocol must verify that all the **Participants** have successfully completed...
their end of the Transaction. Most of the time this will be true and the flow will then move up to the higher-level Process. But it is possible that one of the Participants may end up with a problem that causes a Cancel or a Hazard. In this case, the flow will then move to the appropriate Intermediate Event, even though it had apparently finished successfully.

**Ad-Hoc Sub-Process**

An Ad-Hoc Sub-Process is a specialized type of Sub-Process that is a group of Activities that have no required sequence relationships. A set of activities can be defined for the Process, but the sequence and number of performances for the Activities is determined by the performers of the Activities.

A Sub-Process is marked as being ad-hoc with a “tilde” symbol placed at the bottom center of the Sub-Process shape (see Figure 10-32 and Figure 10-33).

- The marker for an Ad-Hoc Sub-Process MUST be a “tilde” symbol.
- The Ad-Hoc Marker MAY be used in combination with any of the other markers.

![Figure 10-32 – A collapsed Ad-Hoc Sub-Process](image)

![Figure 10-33 – An expanded Ad-Hoc Sub-Process](image)
The Ad-Hoc Sub-Process element inherits the attributes and model associations of Activities (see Table 10-3) through its relationship to Sub-Process. Table 10-22 presents the additional model associations of the Ad-Hoc Sub-Process:

Table 10-22 – Ad-hoc Sub-Process model associations

<td></td>
</tr>
</tbody>
</table>

Activities within the Process are generally disconnected from each other. During execution of the Process, any one or more of the Activities may be active and they may be performed multiple times. The performers determine when Activities will start, what the next Activity will be, and so on.

Examples of the types of Processes that are Ad-Hoc include computer code development (at a low level), sales support, and writing a book chapter. If we look at the details of writing a book chapter, we could see that the Activities within this Process include: researching the topic, writing text, editing text, generating graphics, including graphics in the text, organizing references, etc. (see Figure 10-34). There may be some dependencies between Tasks in this Process, such as writing text before editing text, but there is not necessarily any correlation between an instance of writing text to an instance of editing text. Editing may occur infrequently and based on the text of many instances of the writing text Task.
Although there is no required formal Process structure, some sequence and data dependencies can be added to the details of the Process. For example, we can extend the book chapter Ad-Hoc Sub-Process shown above and add Data Objects, Data Associations, and even Sequence Flow (Figure 10-35).

Ad-Hoc Sub-Processes restrict the use of BPMN elements that would normally be used in Sub-Processes.

- The list of BPMN elements that MUST be used in an Ad-Hoc Sub-Process: Activity.
- The list of BPMN elements that MAY be used in an Ad-Hoc Sub-Process: Data Object, Sequence Flow, Association, Data Association, Group, Message Flow (as a source or target), Gateway, and Intermediate Event.
- The list of BPMN elements that MUST NOT be used in an Ad-Hoc Sub-Process: Start Event, End Event, Conversations (graphically), Conversation Links, and Choreography Activities.
The Data Objects as inputs into the Tasks act as an additional constraint for the performance of those Tasks. The performers still determine when the Tasks will be performed, but they are now constrained in that they cannot start the Task without the appropriate input. The addition of Sequence Flow between the Tasks (e.g., between “Generate Graphics” and “Include Graphics in Text”) creates a dependency where the performance of the first Task must be followed by a performance of the second Task. This does not mean that the second Task must be performed immediately, but there must be a performance of the second Task after the performance of the first Task.

It is a challenge for a BPM engine to monitor the status of Ad-Hoc Sub-Processes, usually these kind of Processes are handled through groupware applications (such as e-mail), but BPMN allows modeling of Processes that are not necessarily executable, although there are some process engines that can follow an Ad-Hoc Sub-Process. Given this, at some point the Ad-Hoc Sub-Process will have complete and this can be determined by evaluating a completionCondition that evaluates Process attributes that will have been updated by an Activity in the Process.

10.2.6. Call Activity

A Call Activity identifies a point in the Process where a global Process or a Global Task is used. The Call Activity acts as a ‘wrapper’ for the invocation of a global Process or Global Task within the execution. The activation of a call Activity results in the transfer of control to the called global Process or Global Task.

The BPMN 2.0 Call Activity corresponds to the Reusable Sub-Process of BPMN 1.2. A BPMN 2.0 Sub-Process corresponds to the Embedded Sub-Process of BPMN 1.2 (see the previous section).

A Call Activity object shares the same shape as the Task and Sub-Process, which is a rectangle that has rounded corners. However, the target of what the Activity calls will determine the details of its shape.

Proposal for:
Business Process Model and Notation (BPMN), v2.0
- If the Call Activity calls a Global Task, then the shape will be the same as a Task, but the boundary of the shape will MUST have a thick line (see Figure 10-36).
- The Call Activity MUST display the marker of the type of Global Task (e.g., the Call Activity would display the User Task marker if calling a Global User Task).
- If the Call Activity calls a Process, then there are two (2) options:
  - The details of the called Process can be hidden and the shape of the Call Activity will be the same as a collapsed Sub-Process, but the boundary of the shape MUST have a thick line (see Figure 10-37).
  - If the details of the called Process are available, then the shape of the Call Activity will be the same as a expanded Sub-Process, but the boundary of the shape MUST have a thick line (see Figure 10-38).

![Figure 10-36 – A Call Activity object calling a Global Task](image)

![Figure 10-37 – A Call Activity object calling a Process (Collapsed)](image)

![Figure 10-38 – A Call Activity object calling a Process (Expanded)](image)

When a Process with a definitional Collaboration, calls a Process that also has a definitional Collaboration, the Participants of the two (2) Collaborations can be matched to each other using ParticipantAssociations of the Collaboration of the calling Process.
Since Call Activities rely in the CallableElement being invoked (see Figure 10-39), Call Activities must not define their own data inputs, InputSets, and outputs, OutputSets but use the data inputs, InputSets, and outputs, OutputSets defined in the referenced CallableElement.

![Call Activity class diagram](image)

**Figure 10-39 – The Call Activity class diagram**

A Call Activity can override properties and attributes of the element being called, potentially changing the behavior of the called element based on the calling context. Also, Events that are propagated along the hierarchy (errors and escalations) are propagated from the called element to the Call Activity (and can be handled on its boundary).

The Call Activity inherits the attributes and model associations of Activity (see Table 10-3). Table 10-23 presents the additional model associations of the CallActivity:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>calledElement: CallableElement [0..1]</td>
<td>The element to be called, which will be either a Process or a GlobalTask. Other CallableElements, such as Choreography, GlobalChoreographyTask, Conversation, and GlobalCommunication MUST NOT be called by the Call Conversation element.</td>
</tr>
</tbody>
</table>

**10.2.7. Global Task**

A Global Task is a reusable, atomic Task definition that can be called from within any Process by a Call Activity.
Types of Global Task

There are different types of Tasks identified within BPMN to separate the types of inherent behavior that Tasks might represent. This is true for both Global Tasks and standard Tasks, where the list of Task types is the same for both. For the sake of efficiency in this specification, the list of Task types is presented once on page 167. The behavior, attributes, and model associations defined in that section also apply to the types of Global Tasks.

10.2.8. Loop Characteristics

Activities may be repeated sequentially, essentially behaving like a loop. The presence of LoopCharacteristics signifies that the Activity has looping behavior. LoopCharacteristics is an abstract class. Concrete subclasses define specific kinds of looping behavior.

The LoopCharacteristics inherits the attributes and model associations of BaseElement (see Table 8-5). There are no further attributes or model associations of the LoopCharacteristics.

However, each Loop Activity Instance has attributes whose values may be referenced by Expressions. These values are only available when the Loop Activity is being executed.
Figure 10-41 displays the class diagram for an Activity’s loop characteristics, including the details of both the standard loop and a multi-instance.

The LoopCharacteristics element inherits the attributes and model associations of BaseElement (see Table 8-5), but does not have any further attributes or model associations. However, a Loop Activity does have additional Instance attributes as shown in Table 10-24.

Table 10-24 – Loop Activity Instance attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>loopCounter: integer</td>
<td>The LoopCounter attribute is used at runtime to count the number of loops and is automatically updated by the process engine.</td>
</tr>
</tbody>
</table>

**Standard Loop Characteristics**

The StandardLoopCharacteristics class defines looping behavior based on a boolean condition. The Activity will loop as long as the boolean condition is true. The condition is evaluated for every loop iteration, and may be evaluated at the beginning or at the end of the iteration. In addition, a numeric cap can be optionally specified. The number of iterations may not exceed this cap.

- The marker for a Task or a Sub-Process that is a standard loop MUST be a small line with an
arrowhead that curls back upon itself (see Figure 10-42 and Figure 10-43).

- The loop Marker MAY be used in combination with the Compensation Marker.

![Figure 10-42 – A Task object with a Standard Loop Marker](image)

![Figure 10-43 – A Sub-Process object with a Standard Loop Marker](image)

The StandardLoopCharacteristics element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to LoopCharacteristics. Table 10-25 presents the additional attributes and model associations for the StandardLoopCharacteristics element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>testBefore: boolean</td>
<td>Flag that controls whether the loop condition is evaluated at the beginning (testBefore = true) or at the end (testBefore = false) of the loop iteration.</td>
</tr>
<tr>
<td>loopMaximum: integer</td>
<td>Serves as a cap on the number of iterations.</td>
</tr>
<tr>
<td>loopCondition: Expression</td>
<td>A Boolean expression that controls the loop. The Activity will only loop as long as this condition is true. The looping behavior may be underspecified, meaning that the modeler may simply document the condition, in which case the loop cannot be formally executed.</td>
</tr>
</tbody>
</table>

### Multi-Instance Characteristics

The MultiInstanceLoopCharacteristics class allows for creation of a desired number of Activity instances. The instances may execute in parallel or may be sequential. Either an expression is used to specify or calculate the desired number of instances or a data driven setup can be used. In that case a data input can be specified, which is able to handle a collection of data. The number of items in the collection determines the number of Activity instances. This data input can be produced by a data input association. The modeler can also configure this loop to control the Tokens produced.

- The marker for a Task or Sub-Process that is a multi-instance MUST be a set of three vertical lines.
- If the multi-instance instances are set to be performed in parallel rather than sequential (the
isSequential attribute set to false), then the lines of the marker will vertical (see Figure 10-44).

- If the multi-instance instances are set to be performed in sequence rather than parallel (the isSequential attribute set to true), then the marker will be horizontal (see Figure 10-45).
- The Multi-Instance marker MAY be used in combination with the Compensation marker.

Figure 10-44 – Activity Multi-Instance marker for parallel instances

Figure 10-45 – Activity Multi-Instance marker for sequential instances

The MultiInstanceLoopCharacteristics element inherits the attributes and model associations of BaseElement (see Table 8-5), through its relationship to LoopCharacteristics. Table 10-26 presents the additional attributes and model associations for the MultiInstanceLoopCharacteristics element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isSequential: boolean = False</td>
<td>This attribute is a flag that controls whether the Activity instances will execute sequentially or in parallel.</td>
</tr>
<tr>
<td>loopCardinality: Expression [0..1]</td>
<td>A numeric Expression that controls the number of Activity instances that will be created. This Expression MUST evaluate to an integer. This may be underspecified, meaning that the modeler may simply document the condition. In such a case the loop cannot be formally executed. In order to initialize a valid multi-instance, either the loopCardinality Expression or the loopDataInput MUST be specified.</td>
</tr>
</tbody>
</table>
| **loopDataInput**: DataInput [0..1] | A reference to a DataInput which is part of the Activity’s InputOutputSpecification. This DataInput is used to determine the number of Activity instances, one Activity instance per item in the collection of data stored in that DataInput element.

In order to initialize a valid multi-instance, either the loopCardinalityExpression or the loopDataInput MUST be specified. |
| **loopDataOutput**: DataOutput [0..1] | A reference to a DataOutput which is part of the Activity’s InputOutputSpecification. This DataOutput specifies the collection of data, which will be produced by the multi-instance. |
| **inputDataItem**: Property [0..1] | A Property, representing for every Activity instance the single item of the collection stored in the loopDataInput. This Property can be the source of DataInputAssociation to a data input of the Activity’s InputOutputSpecification. The type of this Property MUST the scalar of the type defined for the loopDataInput. |
| **outputDataItem**: Property [0..1] | A Property, representing for every Activity instance the single item of the collection stored in the loopDataOutput. This Property can be the target of DataOutputAssociation to a data output of the Activity’s InputOutputSpecification. The type of this Property MUST the scalar of the type defined for the loopDataOutput. |
| **behavior**: MultiInstanceBehavior = all { none | one | all | complex } | The attribute behavior acts as a shortcut for specifying when events shall be thrown from an Activity instance that is about to complete. It can assume values of none, one, all, and complex, resulting in the following behavior:

- **none**: the EventDefinition which is associated through the noneEvent association will be thrown for each instance completing;
- **one**: the EventDefinition referenced through the oneEvent association will be thrown upon the first instance completing;
- **all**: no Event is ever thrown; a token is produced after completion of all instances
- **complex**: the complexBehaviorDefinitions are consulted to determine if and which Events to throw.

For the behaviors of none and one, a default SignalEventDefinition will be thrown which automatically carries the current runtime attributes of the MI Activity.

Any thrown Events can be caught by boundary Events on the Multi-Instance Activity. |
complexBehaviorDefinition: ComplexBehaviorDefinition [0..*] Controls when and which Events are thrown in case behavior is set to complex.

completionCondition: Expression [0..1] This attribute defines a Boolean Expression that when evaluated to true, cancels the remaining Activity instances and produces a token.

oneBehaviorEventRef: EventDefinition [0..1] The EventDefinition which is thrown when behavior is set to one and the first internal Activity instance has completed.

noneBehaviorEventRef: EventDefinition [0..1] The EventDefinition which is thrown when the behavior is set to none and an internal Activity instance has completed.

The following table lists all instance attributes available at runtime. For each instance of the Multi-Instance Activity (outer instance), there exist a number of generated (inner) instances of the Activity at runtime.

Table 10-27 – Multi-instance Activity Instance attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>loopCounter: integer</td>
<td>This attribute is provided for each generated (inner) instance of the Activity. It contains the sequence number of the generated instance, i.e., if this value of some instance in n, the instance is the n-th instance that was generated.</td>
</tr>
<tr>
<td>numberOfInstances: integer</td>
<td>This attribute is provided for the outer instance of the Multi-Instance Activity only. This attribute contains the total number of inner instances created for the Multi-Instance Activity.</td>
</tr>
<tr>
<td>numberOfActiveInstances: integer</td>
<td>This attribute is provided for the outer instance of the Multi-Instance Activity only. This attribute contains the number of currently active inner instances for the Multi-Instance Activity. In case of a sequential Multi-Instance Activity, this value can't be greater than 1. For parallel Multi-Instance Activities, this value can't be greater than the value contained in numberOfInstances.</td>
</tr>
<tr>
<td>numberOfCompletedInstances: integer</td>
<td>This attribute is provided for the outer instance of the Multi-Instance Activity only. This attribute contains the number of already completed inner instances for the Multi-Instance Activity.</td>
</tr>
<tr>
<td>numberOfTerminatedInstances: integer</td>
<td>This attribute is provided for the outer instance of the Multi-Instance Activity only. This attribute contains the number of terminated inner instances for the Multi-Instance Activity. The sum of numberOfTerminatedInstances, numberOfCompletedInstances and numberOfActiveInstances always sums up to numberOfInstances.</td>
</tr>
</tbody>
</table>
Complex Behavior Definition

This element controls when and which Events are thrown in case behavior of the Multi-Instance Activity is set to complex.

The ComplexBehaviorDefinition element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 10-28 presents the additional attributes and model associations for the ComplexBehaviorDefinition element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>condition: Formal Expression</td>
<td>This attribute defines a Boolean Expression that when evaluated to true, cancels the remaining Activity instances and produces a token.</td>
</tr>
<tr>
<td>event: ImplicitThrowEvent</td>
<td>If the condition is true, this identifies the Event that will be thrown (to be caught by a boundary Event on the Multi-Instance Activity)</td>
</tr>
</tbody>
</table>

10.2.9. XML Schema for Activities

Table 10-29 – Activity XML schema

```
<xsd:element name="activity" type="tActivity"/>
<xsd:complexType name="tActivity" abstract="true">
   <xsd:complexContent>
      <xsd:extension base="tFlowNode">
         <xsd:sequence>
            <xsd:element ref="ioSpecification" minOccurs="0" maxOccurs="1"/>
            <xsd:element ref="property" minOccurs="0" maxOccurs="unbounded"/>
            <xsd:element ref="dataInputAssociation" minOccurs="0" maxOccurs="unbounded"/>
            <xsd:element ref="dataOutputAssociation" minOccurs="0" maxOccurs="unbounded"/>
            <xsd:element ref="activityResource" minOccurs="0" maxOccurs="unbounded"/>
            <xsd:element ref="loopCharacteristics" minOccurs="0"/>
         </xsd:sequence>
      </xsd:extension>
   </xsd:complexContent>
</xsd:complexType>
```
Table 10-30 – ActivityResource XML schema

```xml
<xsd:element name="activityResource" type="tActivityResource"/>
<xsd:complexType name="tActivityResource">
    <xsd:complexContent>
        <xsd:extension base="tBaseElement">

    <xsd:complexContent>
        <xsd:extension base="tActivity"/>
    </xsd:complexContent>
</xsd:complexType>
```
### 10.3. Items and Data

A traditional requirement of Process modeling is to be able to model the items (physical or information items) that are created, manipulated, and used during the execution of a Process. An import aspect of this is the ability to capture the structure of that data and to query or manipulate that structure.

BPMN does not itself provide a built-in model for describing structure of data or an expression language for querying that data. Instead it formalizes hooks that allow for externally defined data structures and expression languages. In addition, BPMN allows for the co-existence of multiple data structure and expression languages within the same model. The compatibility and verification of these languages is outside the scope of this specification and becomes the responsibility of the tool vendor.

BPMN designates XML Schema and XPath as its default data structure and expression languages respectively, but vendors are free to substitute their own languages.

#### 10.3.1. Data Modeling

A traditional requirement of Process modeling is to be able to model the items (physical or information items) that are created, manipulated, and used during the execution of a Process.

This requirement is realized in BPMN through various constructs: Data Objects, ItemDefinition, Properties, Data Inputs, Data Outputs, Messages, Input Sets, Output Sets, and Data Associations.

### Item-Aware Elements

Several elements in BPMN are subject to store or convey items during process execution. These elements are referenced generally as “item-aware elements.” This is similar to the variable construct common to many languages. As with variables, these elements have a ItemDefinition.

The data structure these elements hold is specified using an associated ItemDefinition. An item-aware element may be underspecified, meaning that the structure attribute of its ItemDefinition is optional if the modeler does not wish to define the structure of the associated data.
The elements in the specification defined as item-aware elements are: Data Objects, Properties, DataInputs and DataOutputs, Messages.

![Diagram](image.png)

**Figure 10-46 – ItemAware class diagram**

The ItemAwareElement element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 10-46 presents the additional model associations of the ItemAwareElement element:

**Table 10-46 – ItemAwareElement model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>itemSubjectRef: ItemDefinition [0..1]</td>
<td>Specification of the items that are stored or conveyed by the ItemAwareElement.</td>
</tr>
<tr>
<td>dataState: DataState [0..1]</td>
<td>A reference to the DataState, which defines certain states for the data contained in the Item.</td>
</tr>
</tbody>
</table>

**Data Objects**

The primary construct for modeling data within the Process flow is the DataObject element. A DataObject has a well-defined lifecycle, with resulting visibility constraints.
DataObject

The DataObject class is an item-aware element. Data Object elements must be contained within Process or Sub-Process elements. Data Object elements are visible in a Process diagram.

![DataObject class diagram](image)

**Figure 10-47 – DataObject class diagram**

The DataObject element inherits the attributes and model associations of FlowElement (see Table 8-45) and ItemAwareElement (Table 10-46). Table 10-47 presents the additional attributes of the DataObject element:

**Table 10-47 – DataObject attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isCollection: Boolean = False</td>
<td>Defines if the Data Object represents a collection of elements. This is a projection of the same attribute of the referenced ItemDefinition.</td>
</tr>
</tbody>
</table>

**States**

Data Object elements can optionally reference a DataState element, which is the state of the data contained in the Data Object (see an example of DataStates used for Data Objects in Figure 7-8). The definition of these states, e.g. possible values and any specific semantic are out of scope of this specification.
Therefore, BPMN adopters can use the State element and the BPMN extensibility capabilities to define their states.

The DataState element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 10-48 presents the additional attributes and model associations of the DataObject element:

**Table 10-48 – DataState attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: String</td>
<td>Defines the name of the DataState.</td>
</tr>
</tbody>
</table>

**Data Objects representing a Collection of Data**

A DataObject element that references an ItemDefinition marked as *collection* has to be visualized differently, compared to single *instance* data structures. The notation looks as follows:

Single *instance* (see Figure 10-48)

![Figure 10-48 – A DataObject](image)

Collection (see Figure 10-49)

![Figure 10-49 – A DataObject that is a collection](image)

**Visual representations of Data Objects**

Data Object can appear multiple times in a Process diagram. Each of these appearances references the same Data Object *instance*. Multiple occurrences of a Data Object in a diagram are allowed to simplify diagram connections.

**Lifecycle and Visibility**

The lifecycle of a Data Object is tied to the lifecycle of its parent Process or Sub-Process. When a Process or Sub-Process is instantiated, all Data Objects contained within it are also instantiated. When a Process or Sub-Process *instance* is disposed, all Data Object *instances* contained within it are also disposed. At this point the data within these *instances* are no longer available.
The visibility of a **Data Object** is driven by its lifecycle. The data within a **Data Object** can only be accessed when there is guaranteed to be a live **Data Object instance** present. As a result, a **Data Object** can only be accessed by its immediate parent (**Process** or **Sub-Process**), or by its sibling Flow Elements and their children.

For example: Consider the follow structure.

```
Process A
  Data object 1
  Task A
  Sub-process A
    Data object 2
    Task B
  Sub-process B
    Data object 3
    Sub-process C
      Data object 4
      Task C
  Task D
```

“Data object 2” is visible to: “Sub-Process A” and “Task B.”

“Data object 3” is visible to: “Sub-Process B,” “Sub-Process C,” “Task C,” and “Task D.”

“Data object 4” is visible to: “Sub-Process C” and “Task C.”

**Data Stores**

A **DataStore** provides a mechanism for **Activities** to retrieve or update stored information that will persist beyond the scope of the **Process**. The same **DataStore** can be visualized, through a **Data Store Reference**, in one (1) or more places in the **Process**.

The **Data Store Reference** is an **ItemAwareElement** and can thus be used as the source or target for a **Data Association**. When data flows into or out of a **Data Store Reference**, it is effectively flowing into or out of the **DataStore** that is being referenced.

The notation looks as follows:

![Figure 10-50 – A Data Store](image)
The DataStore element inherits the attributes and model associations of FlowElement (see Table 8-45) through its relationship to RootElement, and ItemAwareElement (see Table 10-46). Table 10-49 presents the additional attributes of the DataStore element:

Table 10-49 – Data Store attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>A descriptive name for the element.</td>
</tr>
<tr>
<td>capacity: Integer [0..1]</td>
<td>Defines the capacity of the Data Store. This is not needed if the isUnlimited attribute is set to true</td>
</tr>
<tr>
<td>isUnlimited: Boolean = False</td>
<td>If isUnlimited is set to true, then the capacity of a Data Store is set as unlimited and will override any value of the capacity attribute.</td>
</tr>
</tbody>
</table>
The **Data Store Reference** element inherits the attributes and model associations of **FlowElement** (see Table 8-45) and **ItemAwareElement** (see Table 10-46). Table 10-49 presents the additional model associations of the **Data Store Reference** element.

**Table 10-50 – Data Store attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataStoreRef: DataStore</td>
<td>Provides the reference to a global <strong>DataStore</strong>.</td>
</tr>
</tbody>
</table>

**Properties**

Properties, like **Data Objects**, are item-aware elements. But, unlike **Data Objects**, they are not visible within a **Process** diagram. Certain flow elements may contain properties, in particular only **Processes**, **Activities** and **Events** may contain **Properties**.

The **Property** class is a **DataElement** element that acts as a container for data associated with flow elements. **Property** elements must be contained within a **FlowElement**. **Property** elements are NOT visible in a **Process** diagram.

**Figure 10-52 – Property class diagram**

The **Property** element inherits the attributes and model associations of **ItemAwareElement** (Table 10-46). Table 10-47 presents the additional attributes of the **Property** element.

**Table 10-51 – Property attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: String</td>
<td>Defines the name of the <strong>Property</strong>.</td>
</tr>
</tbody>
</table>
**Lifecycle and Visibility**

The lifecycle of a Property is tied to the lifecycle of its parent Flow Element. When a Flow Element is instantiated, all Properties contained by it are also instantiated. When a Flow Element instance is disposed, all Property instances contained by it are also disposed. At this point the data within these instances are no longer available.

The visibility of a Property is driven by its lifecycle. The data within a Property can only be accessed when there is guaranteed to be a live Property instance present. As a result, a Property can only be accessed by its parent Flow Element or, when its parent Flow Element is a Process or Sub-Process, then by the immediate children of that Process or Sub-Process.

For example: Consider the follow structure.

```
Process A
  Task A
  Sub-Process A
    Task B
  Sub-Process B
    Sub-Process C
      Task C
    Task D
```

The Properties of “Process A” are visible to: All elements (including children elements) of this Process

The Properties of “Sub-Process A” are visible to: “Sub-Process A” and “Task B.”

The Properties of “Task C” are visible to: “Task C.”

**Data Inputs and Outputs**

Activities and Processes often required data in order to execute. In addition they may produce data during or as a result of execution. Data requirements are captured as Data Inputs and Input Sets. Data that is produced is captured using Data Outputs and Output Sets. These elements are aggregated in a InputOutputSpecification class.

Certain Activities and CallableElements contain a InputOutputSpecification element to describe their data requirements. Execution semantics are defined for the input/output specification and they apply the same way to all elements that extend it. Not every Activity type defines inputs and outputs, only Tasks, CallableElements (Global Tasks and Processes) can define their data requirements.
Figure 10-53 – InputOutputSpecification class diagram
The \textit{InputOutputSpecification} element inherits the attributes and model associations of \textit{BaseElement} (see Table 8-5). Table 10-52 presents the additional attributes and model associations of the \textit{InputOutputSpecification} element:

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Attribute Name} & \textbf{Description/Usage} \\
\hline
\texttt{inputSets: InputSet [1..*]} & A reference to the \textit{InputSets} defined by the \textit{InputOutputSpecification}. Every \textit{InputOutputSpecification} must define at least one \textit{InputSet}. \\
\hline
\texttt{outputSets: OutputSet [1..*]} & A reference to the \textit{OutputSets} defined by the \textit{InputOutputSpecification}. Every Data Interface must define at least one \textit{OutputSet}. \\
\hline
\texttt{dataInputs: DataInput [0..*]} & An optional reference to the Data Inputs of the \textit{InputOutputSpecification}. If the \textit{InputOutputSpecification} defines no Data Input, it means no data is required to start the Activity. \\
\hline
\texttt{dataOutputs: DataOutput [0..*]} & An optional reference to the Data Outputs of the \textit{InputOutputSpecification}. If the \textit{InputOutputSpecification} defines no Data Output, it means no data is required to finish the Activity. \\
\hline
\end{tabular}
\end{table}

\textbf{DataInput}

A \textit{DataInput} is a declaration that a particular kind of data will be used as input of the \textit{InputOutputSpecification}. There may be multiple data inputs associated with an \textit{InputOutputSpecification}.

The \textit{DataInput} is an item-aware element. \textit{DataInput} elements may appear in a \textit{Process} diagram to show the inputs to the \textit{Process} as whole, which are passed along as the inputs of \textit{Activities} by \textit{DataAssociations}.

- \textit{DataInputs} have the same notation as \textit{DataObjects}, except MUST contain a small, unfilled block arrow (see Figure 10-54).
- \textit{DataInputs} MUST NOT have \textit{incoming} \textit{DataAssociations}.

\begin{figure}[h]
\centering
\includegraphics[width=0.2\textwidth]{datainput.png}
\caption{A DataInput}
\end{figure}
The “optional” attribute defines if a DataInput is valid even if the state is “unavailable”. The default value is false. If the value of this attribute is true, then the execution of the Activity will not begin until a value is assigned to the DataInput element, through the corresponding Data Associations.

**States**

DataInput elements can optionally reference a DataState element, which is the state of the data contained in the DataInput. The definition of these states, e.g. possible values, and any specific semantics are out of scope of this specification. Therefore, BPMN adopters can use the DataState element and the BPMN extensibility capabilities to define their states.

**Figure 10-55 – Data Input class diagram**
The **DataInput** element inherits the attributes and model associations of **BaseElement** (see Table 8-5) and **ItemAwareElement** (Table 10-46). Table 10-53 presents the additional attributes and model associations of the **DataInput** element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name</strong>: string</td>
<td>A descriptive name for the element.</td>
</tr>
<tr>
<td><strong>inputSetRefs</strong>: InputSet [1..*]</td>
<td>A <strong>DataInput</strong> is used in one (1) or more <strong>InputSets</strong>. This attribute is derived from the <strong>InputSets</strong>.</td>
</tr>
<tr>
<td><strong>inputSetWithOptional</strong>: InputSet [0..*]</td>
<td>Each <strong>InputSet</strong> that uses this <strong>DataInput</strong> can determine if the Activity can start executing with this <strong>DataInput</strong> state in “unavailable”. This attribute lists those <strong>InputSets</strong>.</td>
</tr>
<tr>
<td><strong>inputSetWhileExecuting</strong>: Inputset [0..*]</td>
<td>Each <strong>InputSet</strong> that uses this <strong>DataInput</strong> can determine if the Activity can evaluate this <strong>DataInput</strong> while executing. This attribute lists those <strong>InputSets</strong>.</td>
</tr>
<tr>
<td><strong>isCollection</strong>: Boolean = False</td>
<td>Defines if the <strong>DataInput</strong> represents a collection of elements. This is a projection of the same attribute of the referenced <strong>ItemDefinition</strong>.</td>
</tr>
</tbody>
</table>

**DataOutput**

A **DataOutput** is a declaration that a particular kind of data may be produced as output of the **InputOutputSpecification**. There may be multiple **DataOutput**s associated with a **InputOutputSpecification**.  

The **DataOutput** is an item-aware element. **DataOutput** elements appear in a **Process** diagram to show the outputs of the **Process** as whole, which are passed along from the outputs of **Activities** by **DataAssociations**.

- **DataOutputs** have the same notation as **DataObjects**, except MUST contain a small, filled block arrow (see Figure 10-54).
- **DataOutputs** MUST NOT have outgoing **DataAssociations**.

![Figure 10-56 – A Data Output](image)

**States**
DataOutput elements can optionally reference a DataState element, which is the state of the data contained in the DataOutput. The definition of these states, e.g. possible values, and any specific semantics are out of scope of this specification. Therefore, BPMN adopters can use the DataState element and the BPMN extensibility capabilities to define their states.

**Figure 10-57 – Data Output class diagram**
The **DataOutput** element inherits the attributes and model associations of **BaseElement** (see Table 8-5) and **ItemAwareElement** (Table 10-46) Table 10-54 presents the additional attributes and model associations of the **DataInput** element:

**Table 10-54 – DataOutput attributes and associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>name: String</code></td>
<td>A descriptive name for the element.</td>
</tr>
<tr>
<td><code>outputSetRefs: OutputSet [1..*]</code></td>
<td>A <strong>DataOutput</strong> is used in one (1) or more <strong>OutputSets</strong>. This attribute is derived from the <strong>OutputSets</strong>.</td>
</tr>
<tr>
<td><code>outputSetwithOptional: OutputSet [0..*]</code></td>
<td>Each <strong>OutputSet</strong> that uses this <strong>DataOutput</strong> can determine if the <strong>Activity</strong> can complete executing without producing this <strong>DataInput</strong>. This attribute lists those <strong>OutputSets</strong>.</td>
</tr>
<tr>
<td><code>outputSetWithWhileExecuting: OutputSet [0..*]</code></td>
<td>Each <strong>OutputSet</strong> that uses this <strong>DataInput</strong> can determine if the <strong>Activity</strong> can produce this <strong>DataOutput</strong> while executing. This attribute lists those <strong>OutputSets</strong>.</td>
</tr>
<tr>
<td><code>isCollection: Boolean = False</code></td>
<td>Defines if the <strong>DataOutput</strong> represents a collection of elements. This is a projection of the same attribute of the referenced <strong>ItemDefinition</strong>.</td>
</tr>
</tbody>
</table>

The following describes the mapping of data inputs and outputs to the specific **Activity** implementations:

**Service Task Mapping**

There is a single data input that has an **ItemDefinition** equivalent to the one defined by the **Message** referred by the `inMessageRef` attribute of the operation.

In the case the operation defines output **Messages**, there is a single data output that has an **ItemDefinition** equivalent to the one defined by **Message** referred by the `outMessageRef` attribute of the operation.

**User Task Mapping**

**User Tasks** have access to the **Data Input**, **Data Output** and the data aware elements available in the scope of the **User Task**.

**Call Activity Mapping**

Since **Call Activities** rely in the callable element being invoked, the data inputs and outputs of the **Call Activity** must match with the data inputs, inputsets and outputs, outputsets defined in the callable element. The data inputs and outputs of the **Call Activity** are mapped to the corresponding data inputs and output of the Callable Element without any explicit data association.
**Script Task Mapping**

**Script Tasks** have access to the **Data Input**, **Data Output** and the data aware elements available in the scope of the **Script Task**.

**InputSet**

An **InputSet** is a collection of **Data Input** elements that together define a valid set of data inputs for a **InputOutputSpecification**. A **InputOutputSpecification** must have at least one **InputSet** element. An **InputSet** may reference zero or more **Data Input** elements. A single **Data Input** may be associated with multiple **InputSet** elements, but it must always be referenced by at least one **InputSet**.

An “empty” **InputSet**, one that references no **Data Input** elements, signifies that the **Activity** requires no data to start executing (this implies that either there are no data inputs or they are referenced by another input set).

**InputSet** elements are contained by **InputOutputSpecification** elements; the order in which these elements are included defines the order in which they will be evaluated.

![InputSet class diagram](image)

**Figure 10-58 – InputSet class diagram**
The `InputSet` element inherits the attributes and model associations of `BaseElement` (see Table 8-5). Table 10-55 presents the additional attributes and model associations of the `InputSet` element:

**Table 10-55 – InputSet attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>A descriptive name for the input set.</td>
</tr>
<tr>
<td>dataInputRefs:</td>
<td>The DataInput elements that collectively make up this data requirement.</td>
</tr>
<tr>
<td>DataInput [0..*]</td>
<td></td>
</tr>
<tr>
<td>optionalInput:</td>
<td>The DataInput elements that are a part of the InputSet that can be in the state of “unavailable” when the Activity starts executing. This association MUST NOT reference a DataInput that is not listed in the dataInputRefs.</td>
</tr>
<tr>
<td>DataInput [0..*]</td>
<td></td>
</tr>
<tr>
<td>whileExecutingInput:</td>
<td>The DataInput elements that are a part of the InputSet that can be evaluated while the Activity is executing. This association MUST NOT reference a DataInput that is not listed in the dataInputRefs.</td>
</tr>
<tr>
<td>DataInput [0..*]</td>
<td></td>
</tr>
<tr>
<td>outputSetRefs:</td>
<td>Specifies an Input/Output rule that defines which OutputSet is expected to be created by the Activity when this InputSet became valid.</td>
</tr>
<tr>
<td>OutputSet [0..*]</td>
<td></td>
</tr>
</tbody>
</table>

**OutputSet**

An `OutputSet` is a collection of `DataOutput` elements that together may be produced as output from an `Activity` or `Event`. An `InputOutputSpecification` element must define at least one `OutputSet` element. An `OutputSet` may reference zero or more `DataOutput` elements. A single `DataOutput` may be associated with multiple `OutputSet` elements, but it must always be referenced by at least one `OutputSet`.

An “empty” `OutputSet`, one that is associated with no `DataOutput` elements, signifies that the `ACTIVITY` may produce no data.

The implementation of the element where the `OutputSet` is defined must determine the `OutputSet` that will be produced. So it is up to the `Activity` implementation or the `Event`, to define which `OutputSet` will be produced.
The **OutputSet** element inherits the attributes and model associations of **BaseElement** (see Table 8-5). Table 10-56 presents the additional attributes and model associations of the **OutputSet** element:

**Table 10-56 – OutputSet attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>A descriptive name for the input set.</td>
</tr>
<tr>
<td>dataOutputRefs: DataOutput [0..*]</td>
<td>The DataOutput elements that may collectively be outputted.</td>
</tr>
<tr>
<td>optionalOutput: DatalInput [0..*]</td>
<td>The DataOutput elements that are a part of the OutputSet that do not have to be produced when the Activity completes executing. This association MUST NOT reference a DataOutput that is not listed in the dataOutputRefs.</td>
</tr>
<tr>
<td>whileExecutingOutput: DatalInput [0..*]</td>
<td>The DataOutput elements that are a part of the OutputSet that can be produced while the Activity is executing. This association MUST NOT reference a DataOutput that is not listed in the dataOutputRefs.</td>
</tr>
<tr>
<td>inputSetRefs: InputSet [0..*]</td>
<td>Specifies an Input/Output rule that defines which InputSet has to become valid to expect the creation of this OutputSet. This attribute is paired with the outputSetRefs attribute of InputSets. This combination replaces the IORules attribute for Activities in BPMN 1.2.</td>
</tr>
</tbody>
</table>
Data Associations

Data Associations are used to move data between Data Objects, Properties, and inputs and outputs of Activities, Processes, and Global Tasks. Tokens do not flow along a Data Association, and as a result they have no direct effect on the flow of the Process.

The purpose of retrieving data from Data Objects or Process Data Inputs is to fill the Activities inputs and later push the output values from the execution of the Activity back into Data Objects or Process Data Outputs.

DataAssociation

The DataAssociation class is a BaseElement contained by an Activity or Event, used to model how data is pushed into or pulled from item-aware elements. DataAssociation elements have one or more sources and a target; the source of the association is copied into the target.

The ItemDefinition from the sourceRef and targetRef must have the same ItemDefinition or the DataAssociation MUST have a transformation Expression that transforms the source ItemDefinition into the target ItemDefinition.

![DataAssociation class diagram](image_url)

Figure 10-60 – DataAssociation class diagram

Optionally, Data Associations can be visually represented in the diagram by using the Association connector style.
The core concepts of a Data Association are that they have sources, a target and an optional transformation.

When a data association is “executed”, data is copied to the target. What is copied depends if there is a transformation defined or not.

If there is no transformation defined or referenced, then only one source must be defined, and the contents of this source will be copied into the target.

If there is a transformation defined or referenced, then this transformation expression will be evaluated and the result of the evaluation is copied into the target. There can be zero to many sources defined in this case, but there is no requirement that these sources are used inside the expression.

In any case, sources are used to define if the data association can be “executed”, if any of the sources is in the state of “unavailable”, then the data association cannot be executed, and the Activity or Event where the data association is defined must wait until this condition is met.

Data Associations are always contained within another element that defines when these data associations are going to be executed. Activities define two (2) sets of data associations, while Events define only 1 (one).

For Events, there is only one set, but they are used differently for catch or throw Events. For a catch Event, data associations are used to push data from the Message received into Data Objects and properties. For a throw Event, data associations are used to fill the Message that is being thrown.

As Data Association are used in different stages of the Process and Activity lifecycle, the possible sources and targets vary according to that stage. This defines the scope of possible elements that can be referenced as source and target. For example: when an Activity starts executing, the scope of valid targets include the Activity data inputs, while at the end of the Activity execution, the scope of valid sources include Activity data outputs.
The `DataAssociation` element inherits the attributes and model associations of `BaseElement` (see Table 8-5). Table 10-57 presents the additional model associations of the `DataAssociation` element:

**Table 10-57 – DataAssociation model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>transformation:</code></td>
<td>Specifies an optional transformation expression. The actual scope of visible data for that expression is defined by the source and target of the specific data association types.</td>
</tr>
<tr>
<td><code>assignment:</code></td>
<td>Specifies one or more data elements <code>Assignments</code>. By using an <code>Assignment</code>, single data structure elements can be assigned from the source structure to the target structure.</td>
</tr>
<tr>
<td><code>sourceRef: ItemAwareElement</code></td>
<td>Identifies the source of the data association. The source must be an <code>ItemAwareElement</code>.</td>
</tr>
<tr>
<td><code>targetRef: ItemAwareElement</code></td>
<td>Identifies the target of the data association. The target must be an <code>ItemAwareElement</code>.</td>
</tr>
</tbody>
</table>

**Assignment**

The `Assignment` class is used to specify a simple mapping of data elements using a specified expression language.

The default expression language for all expressions is specified in the `Definitions` element, using the `expressionLanguage` attribute. It can also be overridden on each individual `Assignment` using the same attribute.

The `Assignment` element inherits the attributes and model associations of `BaseElement` (see Table 8-5). Table 10-58 presents the additional attributes of the `Assignment` element:

**Table 10-58 – Assignment attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>language: string</code></td>
<td>When included, this will override the <code>Expression</code> language specified in the <code>Definitions</code>.</td>
</tr>
<tr>
<td><code>from: Element</code></td>
<td>The body of the <code>Expression</code> that evaluates the source of the <code>Assignment</code>.</td>
</tr>
<tr>
<td><code>to: Element</code></td>
<td>The body of the <code>Expression</code> that defines the actual <code>Assignment</code> operation and the target data element.</td>
</tr>
</tbody>
</table>

**DataInputAssociation**

Proposal for:
Business Process Model and Notation (BPMN), v2.0 230
The **DataInputAssociation** can be used to associate a item-aware element with a **DataInput** contained in an **Activity**. The source of such a **DataAssociation** can be every item-aware element visible to the current scope, e.g. a **Data Object**, a **Property** or an **Expression**.

The **DataInputAssociation** element inherits the attributes and model associations of **FlowElement** (see Table 10-57) but does not contain any additional attributes or model associations.

**DataOutputAssociation**

The **DataOutputAssociation** can be used to associate a **DataOutput** contained within an **ACTIVITY** with any item-aware element visible to the scope the association will be executed in. The target of such a **DataAssociation** can be every item-aware element visible to the current scope, e.g. a **Data Object**, a **Property** or an **Expression**.

The **DataOutputAssociation** element inherits the attributes and model associations of **FlowElement** (see Table 10-57) but does not contain any additional attributes or model associations.

**Data Objects associated with a Sequence Flow**

**Figure 10-63** repeats **Figure 10-62** above, and shows how **Data Associations** are used to represent inputs and outputs of **Activities**.

![Figure 10-63 - A Data Object shown as an output and an inputs](image)

Alternatively, **Data Objects** may be directly associated with a **Sequence Flow** connector (see **Figure 10-64**) to represent the same input/output relationships. This is a visual short cut that normalizes two **Data Associations** (e.g., as seen in **Figure 10-63**, above): one from a item-aware element (e.g., an **Activity**) contained by the source of the **Sequence Flow**, connecting to the **Data Object**; and the other from the **Data Object** connecting to a item-aware element contained by the target of the **Sequence Flow**.
10.3.2. Execution Semantics for Data

When an element that defines a InputOutputSpecification is ready to begin execution by means of Sequence Flow or Event being caught, the inputs of the interface are filled with data coming from elements in the context, such as Data Objects or Properties. The way to represent these assignments is the Data Association elements.

Each defined InputSet element will be evaluated in the order they are included in the InputOutputSpecification.

For each InputSet, the data inputs it references will be evaluated if it is valid.

All data associations that define as target the data input will be evaluated, and if any of the sources of the data association is "unavailable", then the InputSet is "unavailable" and the next InputSet is evaluated.

The first InputSet where all data inputs are “available” (by means of data associations) is used to start the execution of the Activity. If no InputSet is “available”, then the execution will wait until this condition is met.

The time and frequency of when and how often this condition is evaluated is out of scope this specification. Implementations will wait for the sources of data associations to become available and then re-evaluate the InputSets.

10.3.3. Usage of Data in XPath Expressions

BPMN extensibility mechanism enables the usage of various languages for expressions and queries. This section describes how XPath is used in BPMN. It introduces a mechanism to access BPMN Data Objects, BPMN Properties, and various instance attributes from XPath expressions.

The visibility to the Expression language is defined based on the entities visibility to the Activity that contains the expression. All elements visible from the enclosing element of an XPath expression must be made available to the XPath processor.

BPMN Data Objects and BPMN Properties are defined using ItemDefinition. The XPath binding assumes that the ItemDefinition is either an XSD complex type or an XSD element. If XSD element is used it must be manifested as a node-set XPath variable with a single member node. If XSD complex type is used it must be manifested as a node-set XPath variable with one member node containing the anonymous document element that contains the actual value of the BPMN Data Object or Property.
Access to BPMN Data Objects

The table below introduces an XPath function used to access BPMN Data Objects. Argument processName names Process and is of type string. Argument dataObjectName names Data Object and is of type string. It must be a literal string.

Table 10-59 – XPath Extension Function for Data Objects

<table>
<thead>
<tr>
<th>XPath Extension Function</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Element getDataObject (‘processName’, ‘dataObjectName’)</td>
<td>This extension function returns value of submitted Data Object. Argument processName is optional. If omitted, the process enclosing the activity that contains the expression is assumed. In order to access Data Objects defined in a parent process the processName must be used. Otherwise it must be omitted.</td>
</tr>
</tbody>
</table>

Because XPath 1.0 functions do not support returning faults, an empty node set is returned in the event of an error.

Access to BPMN Data Input and Data Output

The table below introduces XPath functions used to access BPMN Data Inputs and BPMN Data Outputs. Argument dataInputName names a Data Input and is of type string. Argument dataOutput names a Data Output and is of type string.

Table 10-60 – XPath Extension Function for Data Inputs and Data Outputs

<table>
<thead>
<tr>
<th>XPath Extension Function</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Element getDataInput(‘dataInputName’)</td>
<td>This extension function returns the value of the submitted Data Input.</td>
</tr>
<tr>
<td>Element getDataOutput(‘dataOutputName’)</td>
<td>This extension function returns the value of the submitted Data Output.</td>
</tr>
</tbody>
</table>

Access to BPMN Properties

The table below introduces XPath functions used to access BPMN Properties.

Argument processName names Process and is of type string. Argument propertyName names property and is of type string. Argument activityName names Activity and is of type string. Argument eventName names Event and is of type string. These strings must be literal strings. The XPath extension functions return value of the submitted property.

Because XPath 1.0 functions do not support returning faults, an empty node set is returned in the event of an error.
### Table 10-61 – XPath Extension Functions for Properties

<table>
<thead>
<tr>
<th>XPath Extension Function</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Element <code>getProcessProperty</code> ('processName', 'propertyName')</td>
<td>This extension function returns value of submitted Process property. Argument <code>processName</code> is optional. If omitted, the process enclosing the activity that contains the expression is assumed. In order to access Properties defined in a parent process the <code>processName</code> must be used. Otherwise it must be omitted.</td>
</tr>
<tr>
<td>Element <code>getActivityProperty</code> ('activityName', 'propertyName')</td>
<td>This extension function returns value of submitted Activity property.</td>
</tr>
<tr>
<td>Element <code>getEventProperty</code> ('eventName', 'propertyName')</td>
<td>This extension function returns value of submitted Event property.</td>
</tr>
</tbody>
</table>

### For BPMN Instance Attributes

The table below introduces XPath functions used to access BPMN Instance Attributes.

Argument `processName` names **Process** and is of type **string**. Argument `attributeName` names Instance attribute and is of type **string**. Argument `activityName` names **Activity** and is of type **string**. These strings must be literal strings.

These functions return value of the submitted *instance* Activity. Because XPath 1.0 functions do not support returning faults, an empty node set is returned in the event of an error.

### Table 10-62 – XPath Extension Functions for Instance Attributes

<table>
<thead>
<tr>
<th>XPath Extension Function</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Element <code>getProcessInstanceAttribute</code> ('processName', 'attributeName')</td>
<td>This extension function returns value of submitted Process instance attribute. Argument <code>processName</code> is optional. If omitted, the process enclosing the activity that contains the expression is assumed. In order to access Instance Attributes of a parent process the <code>processName</code> must be used. Otherwise it must be omitted.</td>
</tr>
<tr>
<td>Element <code>getChoreographyInstanceAttribute</code> ('attributeName')</td>
<td>This extension function returns value of submitted Choreography instance attribute.</td>
</tr>
<tr>
<td>Element <code>getActivityInstanceAttribute</code> ('activityName', 'attributeName')</td>
<td>This extension function returns value of submitted Activity instance attribute. User Task and Loop are examples of activities.</td>
</tr>
</tbody>
</table>
10.3.4. XML Schema for Data

Table 10-63 – Assignment XML schema

```xml
<xsd:element name="assignment" type="tAssignment" />
<xsd:complexType name="tAssignment">
    <xsd:complexContent>
        <xsd:extension base="tBaseElement">
            <xsd:sequence>
                <xsd:element name="from" type="tBaseElementWithMixedContent" minOccurs="1" maxOccurs="1"/>
                <xsd:element name="to" type="tBaseElementWithMixedContent" minOccurs="1" maxOccurs="1"/>
            </xsd:sequence>

    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
```
10.4. Events

An Event is something that “happens” during the course of a Process. These Events affect the flow of the Process and usually have a cause or an impact and in general require or allow for a reaction. The term “event” is general enough to cover many things in a Process. The start of an Activity, the end of an Activity, the change of state of a document, a Message that arrives, etc., all could be considered Events.

Events allow for the description of “event-driven” Processes. In these Processes, there are three main types of Events:

- **Start Events** (see page 244) which indicate where a Process will start.
- **End Events** (see page 252) which indicate where a path of a Process will end.
- **Intermediate Events** (see page 256) which indicate where something happens somewhere between the start and end of a Process.

Within these three types, Events come in two flavors:

- **Events** that *catch a Trigger*. All Start Events and some Intermediate Events are catching Events.
- **Events** that *throw a Result*. All End Events and some Intermediate Events are throwing Events that may eventually be *caught* by another Event. Typically the *Trigger* carries information out of the scope where the *throw Event* occurred into the scope of the catching Events. The *throwing* of a *trigger* may be either implicit as defined by this standard or an extension to it or explicit by a *throw Event*. 

10.4.1. Concepts

Depending on the type of the Event there are different strategies to forward the trigger to catching Events: publication, direct resolution, propagation, cancellations, and compensations.

With publication a trigger may be received by any catching Events in any scope of the system where the trigger is published. Events for which publication is used are grouped to Conversations. Published Events may participate in several Conversations. Messages are triggers, which are generated outside of the Pool they are published in. They typically describe B2B communication. When Messages need to reach a specific Process instance, correlation is used to identify the particular instance. Signals are triggers generated in the Pool they are published.

Timer and Conditional triggers are implicitly thrown. When they are activated they wait for a time based or status based condition respectively to trigger the catch Event.

A trigger that is propagated is forwarded from the location where the Event has been thrown to the innermost enclosing scope instance (e.g., Process level) which has an attached Event being able to catch the trigger. Error triggers are critical and suspend execution at the location of throwing. Escalations are non critical and execution continues at the location of throwing. If no catching Event is found for an error or escalation trigger, this trigger is unresolved.

Figure 10-65 – The Event Class Diagram
Termination, compensation, and cancellation are directed towards a Process or a specific Activity instance. Termination indicates that all Activities in the Process or Activity should be immediately ended. This includes all instances of multi-instances. It is ended without compensation or Event handling.

Compensation of a successfully completed Activity triggers its compensation handler. The compensation handler is either user defined or implicit. The implicit compensation handler of a Sub Process calls all compensation handlers of its enclosed Activities in the reverse order of Sequence Flow dependencies. If compensation is invoked for an Activity that has not yet completed, or has not completed successfully, nothing happens (in particular, no error is raised).

Cancellation will terminate all running Activities and compensate all successfully completed Activities in the Sub-Process it is applied to. If the Sub-Process is a Transaction, the Transaction is rolled back.

Data Modeling and Events

Some Events (like the Message, Signal, Error, Escalation and Multiple Event) have the capability to carry data. Data Association is used to push data from a Catch Event to a Data Element. For Throw Events, a Data Association is used to fill the Event data from a Data Element (see page 211 for the definition of Data Elements).

Catch Event Data Association

The Data Association for a Catch Event is performed after the trigger of the Catch Event occurs (Message, Signal, Error, Escalation, Multiple data is available in the Catch Event). The Data Association assigns the data of the Event to a Data Element that is in the scope of the Catch Event. After that, Sequence Flow continues as usual.

For example, consider a Receive Message Intermediate Event; as soon as the Message is received by the Event, the Data Association is performed and the Message data is assigned for example to a Data Object of the Process.

Throw Event Data Association

The Data Association for a Throw Event is performed when the Sequence Flow arrives at the Throw Event. The Data Association assigns the data from a Data Element that is in the scope of the Throw Event to the Event data (Message, Signal, Error, Escalation, and Multiple). After that the trigger of the Event will occur.

For example, consider a Message End Event; when the Sequence Flow reaches the Message End Event, the data association of the Event is performed. The data association assigns data from a Data Element that is in the scope of the Message End Event to the Message. Then the Message is send to a Participant.

Common Catch Event attributes

The following table shows the common attributes for Catch Events.
The CatchEvent element inherits the attributes and model associations of FlowElement (see Table 8-45) through its relationship to the Event element (see page 103). Table 10-75 presents the additional attributes and model associations of the CatchEvent element:

**Table 10-75 – CatchEvent attributes and model associations**

Implicit Throw Event

A sub-type of throw Event is the ImplicitThrowEvent. This is a non-graphical Event that this used for Multi-Instance Activities (see page 201). The ImplicitThrowEvent element inherits the attributes and model associations of ThrowEvent (see Table 10-76) but does not have any additional attributes or model associations.
10.4.2. Start Event

As the name implies, the Start Event indicates where a particular Process will start. In terms of Sequence Flow, the Start Event starts the flow of the Process, and thus, will not have any incoming Sequence Flow—no Sequence Flow can connect to a Start Event.

The Start Event shares the same basic shape of the Intermediate Event and End Event, a circle with an open center so that markers can be placed within the circle to indicate variations of the Event.

- A Start Event is a circle that MUST be drawn with a single thin line (see Figure 10-66).
- The use of text, color, size, and lines for a Start Event MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63 with the exception that:
  - The thickness of the line MUST remain thin so that the Start Event may be distinguished from the Intermediate and End Events.

Figure 10-66 - Start Event

Throughout this document, we discuss how Sequence Flow is used within a Process. To facilitate this discussion, we employ the concept of a token that will traverse the Sequence Flow and pass through the elements in the Process. A token is a theoretical concept that is used as an aid to define the behavior of a Process that is being performed. The behavior of Process elements can be defined by describing how they interact with a token as it “traverses” the structure of the Process.

Note: A token does not traverse the Message Flow since it is a Message that is passed down a Message Flow (as the name implies).

Semantics of the Start Event include:

- A Start Event is OPTIONAL: a Process level—a top-level Process or an expanded Sub-Process—MAY (is no required to) have a Start Event.

Note – A Process may have more than one Process level (i.e., it can include Expanded Sub-Processes). The use of Start and End Events is independent for each level of the Diagram.

- If a Process is complex and/or the starting conditions are not obvious, then it is RECOMMENDED that a Start Event be used
- If a Start Event is not used, then the implicit Start Event for the Process SHALL NOT have a Trigger.
- If there is an End Event, then there MUST be at least one Start Event.
- If the Start Event is used, then there MUST NOT be other flow elements that do not have incoming Sequence Flow—all other Flow Objects MUST be a target of at least one Sequence Flow.
  - Exceptions to this are Activities that are defined as being Compensation Activities (have the Compensation Marker). Compensation Activities MUST NOT have any incoming
Sequence Flow, even if there is a Start Event in the Process level. See page 314 for more information on Compensation Activities.

- An exception to this is the Intermediate Event, which MAY be without an incoming Sequence Flow (when attached to an Activity boundary).

- If the Start Event is not used, then all Flow Objects that do not have an incoming Sequence Flow (i.e., are not a target of a Sequence Flow) SHALL be instantiated when the Process is instantiated. There is an assumption that there is only one implicit Start Event, meaning that all the starting Flow Objects will start at the same time.

- Exceptions to this are Activities that are defined as being Compensation Activities (have the Compensation marker). Compensation Activities are not considered a part of the normal flow and MUST NOT be instantiated when the Process is instantiated. See page 314 for more information on Compensation Activities.

- There MAY be multiple Start Events for a given Process level.

- Each Start Event is an independent Event. That is, a Process instance SHALL be generated when the Start Event is triggered.

If the Process is used as a Sub-Process and there are multiple None Start Events, then when flow is transferred from the parent Process to the Sub-Process, only one of the Sub-Process’s Start Events will be triggered. The TargetRef attribute of the Sequence Flow incoming to the Sub-Process object can be extended to identify the appropriate Start Event.

Note – The behavior of Process may be harder to understand if there are multiple Start Events. It is RECOMMENDED that this feature be used sparingly and that the modeler be aware that other readers of the Diagram may have difficulty understanding the intent of the Diagram.

When the trigger for a Start Event occurs, a new Process will be instantiated and a token will be generated for each outgoing Sequence Flow from that Event.

Start Event Triggers

Start Events can be used for three types of Processes:

- Top-level Processes
- Sub-Processes (embedded and called (reusable))
- Event Sub-Processes.

The next three (3) sections describe the types of Start Events that can be used for each of these three types of Processes.

Start Events for Top-level Processes

There are many ways that top-level Processes can be started (instantiated). The Trigger for a Start Event is designed to show the general mechanisms that will instantiate that particular Process. There are seven (7) types of Start Events for top-level Processes in BPMN (see Table 10-77) None, Message, Timer, Conditional, Signal, Multiple, and Parallel.
### Table 10-77 – Top-Level Process Start Event Types

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The None Start Event does not have a defined trigger. There is no specific EventDefinition subclass (see page 266) for None Start Events. If the Start Event has no associated EventDefinition, then the Event MUST be displayed without a marker (see the figure on the right).</td>
<td><img src="image" alt="None" /></td>
</tr>
<tr>
<td>Message</td>
<td>A Message arrives from a Participant and triggers the start of the Process. See page 112 for more details on Messages. If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass MessageEventDefinition, then the Event is a Message Start Event and MUST be displayed with an envelope marker (see the figure to the right). The actual Participant from which the Message is received can be identified by connecting the Event to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10-1.</td>
<td><img src="image" alt="Message" /></td>
</tr>
<tr>
<td>Timer</td>
<td>A specific time-date or a specific cycle (e.g. every Monday at 9am) can be set that will trigger the start of the Process. If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass TimerEventDefinition, then the Event is a Timer Start Event and MUST be displayed with a clock marker (see the figure to the right).</td>
<td><img src="image" alt="Timer" /></td>
</tr>
<tr>
<td>Conditional</td>
<td>This type of event is triggered when a Condition such as “S&amp;P 500 changes by more than 10% since opening”, or “Temperature above 300C” become true. The Condition Expression for the Event must become false and then true before the Event can be triggered again. If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass ConditionalEventDefinition, then the Event is a Conditional Start Event and MUST be displayed with a lined paper marker (see the figure to the right).</td>
<td><img src="image" alt="Conditional" /></td>
</tr>
<tr>
<td>Signal</td>
<td>A Signal arrives that has been broadcast from another Process and triggers the start of the Process. Note that the Signal is not a Message, which has a specific target for the Message. Multiple Processes can have Start Events that are triggered from the same broadcasted Signal. If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass SignalEventDefinition, then the Event is a Signal Start Event and MUST be displayed with a triangle marker (see the figure to the right).</td>
<td><img src="image" alt="Signal" /></td>
</tr>
</tbody>
</table>
Multiple
This means that there are multiple ways of triggering the Process. Only one of them is required.

There is no specific EventDefinition subclass (see page 266) for Multiple Start Events. If the Start Event has more than one associated EventDefinition, then the Event MUST be displayed with the Multiple Event marker (a pentagon—see the upper figure to the right).

Parallel Multiple
This means that there are multiple triggers required before the Process can be instantiated. All of the types of triggers that are listed in the Start Event MUST be triggered before the Process is instantiated.

There is no specific EventDefinition subclass (see page 266) for Parallel Multiple Start Events. If the Start Event has more than one associated EventDefinition and the parallelMultiple attribute of the Start Event is true, then the Event MUST be displayed with the Parallel Multiple Event marker (an open plus sign—see the figure to the right).

Start Events for Sub-Processes

There is only one (1) type of Start Event for Sub-Processes in BPMN (see Table 10-78): None.

### Table 10-78 – Sub-Process Start Event Types

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The None Start Event is used for all Sub-Processes, either embedded or called (reusable). Other types of Triggers are not used for a Sub-Process, since the flow of the Process (a token) from the parent Process is the Trigger of the Sub-Process. If the Sub-Process is called (reusable) and has multiple Start Events, some of the other Start Events may have Triggers, but these Start Events would not be used in the context of a Sub-Process. When the other Start Events are triggered, they would instantiate top-level Processes.</td>
<td>![None marker]</td>
</tr>
</tbody>
</table>

Start Events for Event Sub-Processes

A Start Event can also initiate an inline Event Sub-Process (see page 188). In that case, the same Event types as for boundary Events are allowed (see Table 10-79), namely: Message, Timer, Escalation, Error, Cancel, Compensation, Conditional, Signal, Multiple, and Parallel.

- An Event Sub-Process MUST have a single Start Event.
### Table 10-79 – Event Sub-Process Start Event Types

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
</table>
| Message   | If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass MessageEventDefinition, then the Event is a Message Start Event and uses an envelope marker (see the figures to the right).

For a Message Event Sub-Process that interrupts its containing Process, the boundary of the Event is solid (see the upper figure to the right).

For a Message Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right).

The actual Participant from which the Message is received can be identified by connecting the Event to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10-1.                                                                                             | *Interrupting*          |
| Timer     | If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass TimerEventDefinition, then the Event is a Timer Start Event and uses a clock marker (see the figures to the right).

For a Timer Event Sub-Process that interrupts its containing Process, the boundary of the Event is solid (see the upper figure to the right).

For a Timer Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right).                                                                                          | *Interrupting*          |
| Escalation| Escalation Event Sub-Processes implement measures to expedite the completion of a business activity, should it not satisfy a constraint specified on its execution (such as a time-based deadline).

The Escalation Start Event is only allowed for triggering an in-line Event Sub-Process.

If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass EscalationEventDefinition, then the Event is an Escalation Start Event and uses an arrowhead marker (see the figures to the right).

For an Escalation Event Sub-Process that interrupts its containing Process, the boundary of the Event is solid (see the upper figure to the right).

For an Escalation Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right).                                                                                         | *Interrupting*          |
<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
<th>Diagram</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>The Error Start Event is only allowed for triggering an in-line Event Sub-Process.</td>
<td><img src="image" alt="Marker" /></td>
</tr>
<tr>
<td></td>
<td>If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass ErrorEventDefinition, then the Event is an Error Start Event and uses a lightning marker (see the figures to the right).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Given the nature of Errors, an Event Sub-Process with an Error trigger will always interrupt its containing Process.</td>
<td></td>
</tr>
<tr>
<td>Compensation</td>
<td>The Compensation Start Event is only allowed for triggering an in-line Compensation Event Sub-Process (see [Compensation Handler] on page 314). This type of Event is triggered when compensation occurs.</td>
<td><img src="image" alt="Marker" /></td>
</tr>
<tr>
<td></td>
<td>If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass CompensationEventDefinition, then the Event is a Compensation Start Event and uses a double triangle marker (see the figure to the right).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>This Event does not interrupt the Process since the Process has to be completed before this Event can be triggered.</td>
<td></td>
</tr>
<tr>
<td>Conditional</td>
<td>If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass ConditionalEventDefinition, then the Event is a Conditional Start Event and uses an lined page marker (see the figures to the right).</td>
<td><img src="image" alt="Marker" /></td>
</tr>
<tr>
<td></td>
<td>For a Conditional Event Sub-Process that interrupts its containing Process, then the boundary of the Event is solid (see the upper figure to the right).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For a Conditional Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right).</td>
<td></td>
</tr>
<tr>
<td>Signal</td>
<td>If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass SignalEventDefinition, then the Event is a Signal Start Event and uses an triangle marker (see the figures to the right).</td>
<td><img src="image" alt="Marker" /></td>
</tr>
<tr>
<td></td>
<td>For a Signal Event Sub-Process that interrupts its containing Process, then the boundary of the Event is solid (see the upper figure to the right).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For a Signal Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right).</td>
<td></td>
</tr>
</tbody>
</table>
### Multiple

A Multiple Event indicates that there are multiple ways of triggering the Event Sub-Process. Only one of them is required to actually start the Event Sub-Process.

There is no specific `EventDefinition` subclass (see page 266) for Multiple Start Events. If the Start Event has more than one associated `EventDefinition`, then the Event MUST be displayed with the Multiple Event marker (a pentagon—see the figures on the right).

For a Multiple Event Sub-Process that interrupts its containing Process, the boundary of the Event is solid (see the upper figure to the right).

For a Multiple Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right).

<table>
<thead>
<tr>
<th>Interrupting</th>
<th>Non-Interrupting</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1" alt="Interrupting" /></td>
<td><img src="image2" alt="Non-Interrupting" /></td>
</tr>
</tbody>
</table>

### Parallel Multiple

A Multiple Event indicates that there are multiple ways of triggering the Event Sub-Process. All of them are required to actually start the Event Sub-Process.

There is no specific `EventDefinition` subclass (see page 266) for Parallel Multiple Start Events. If the Start Event has more than one associated `EventDefinition` and the `parallelMultiple` attribute of the Start Event is `true`, then the Event MUST be displayed with the Parallel Multiple Event marker (an open plus sign—see the figures to the right).

For a Parallel Multiple Event Sub-Process that interrupts its containing Process, the boundary of the Event is solid (see the upper figure to the right).

For a Parallel Multiple Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right).

<table>
<thead>
<tr>
<th>Interrupting</th>
<th>Non-Interrupting</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image3" alt="Interrupting" /></td>
<td><img src="image4" alt="Non-Interrupting" /></td>
</tr>
</tbody>
</table>

### Attributes for Start Events

For Start Events, the following additional attribute exists:
The Start Event element inherits the attributes and model associations of CatchEvent (see Table 10-75). Table 10-80 presents the additional attributes of the Start Event element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isInterrupting: boolean</td>
<td>This attribute only applies to Start Events of Event Sub-Processes; it is ignored for other Start Events. This attribute denotes whether the Sub-Process encompassing the Event Sub-Process should be cancelled or not. If the encompassing Sub-Process is not cancelled, multiple instances of the Event Sub-Process can run concurrently. This attribute cannot be applied to Error Events (where it's always true), or Compensation Events (where it doesn't apply).</td>
</tr>
</tbody>
</table>

### Sequence Flow Connections

See Section “Sequence Flow Connections Rules” on page 64 for the entire set of objects and how they may be source or targets of Sequence Flow.

- A Start Event MUST NOT be a target for Sequence Flow; it MUST NOT have incoming Sequence Flow.
  - An exception to this is when a Start Event is used in an Expanded Sub-Process and is attached to the boundary of that Sub-Process. In this case, a Sequence Flow from the higher-level Process MAY connect to that Start Event in lieu of connecting to the actual boundary of the Sub-Process.
- A Start Event MUST be a source for Sequence Flow.
- Multiple Sequence Flow MAY originate from a Start Event. For each Sequence Flow that has the Start Event as a source, a new parallel path SHALL be generated.
  - The Condition attribute for all outgoing Sequence Flow MUST be set to None.
  - When a Start Event is not used, then all Flow Objects that do not have an incoming Sequence Flow SHALL be the start of a separate parallel path.
  - Each path will have a separate unique token that will traverse the Sequence Flow.

### Message Flow Connections

**Note** – All Message Flow must connect two separate Pools. They can connect to the Pool boundary or to Flow Objects within the Pool boundary. They cannot connect two objects within the same Pool.

See Section “Message Flow Connection Rules” on page 65 for the entire set of objects and how they may be source or targets of Message Flow.

- A Start Event MAY be the target for Message Flow; it can have 0 (zero) or more incoming Message Flow. Each Message Flow arriving at a Start Event represents an instantiation mechanism (a Trigger) for the Process. Only one of the Triggers is required to start a new Process.
o The Trigger attribute of the Start Event MUST be set to Message or Multiple if there are any incoming Message Flow.

o The Trigger attribute of the Start Event MUST be set to Multiple if there are more than one incoming Message Flow.

- A Start Event MUST NOT be a source for Message Flow; it MUST NOT have outgoing Message Flow.

10.4.3. End Event

As the name implies, the End Event indicates where a Process will end. In terms of Sequence Flow, the End Event ends the flow of the Process, and thus, will not have any outgoing Sequence Flow—no Sequence Flow can connect from an End Event.

The End Event shares the same basic shape of the Start Event and Intermediate Event, a circle with an open center so that markers can be placed within the circle to indicate variations of the Event.

- An End Event is a circle that MUST be drawn with a single thick line (see Figure 10-67).

- The use of text, color, size, and lines for an End Event MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63 with the exception that:
  - The thickness of the line MUST remain thick so that the End Event may be distinguished from the Intermediate and Start Events.

Figure 10-67 - End Event

To continue discussing how flow proceeds throughout the Process, an End Event consumes a token that had been generated from a Start Event within the same level of Process. If parallel Sequence Flow targets the End Event, then the tokens will be consumed as they arrive. All the tokens that were generated within the Process must be consumed by an End Event before the Process has been completed. In other circumstances, if the Process is a Sub-Process, it can be stopped prior to normal completion through interrupting Intermediate Events (See Section 10.2.2, “Exception Flow,” on page 131 for more details). In this situation the tokens will be consumed by an Intermediate Event attached to the boundary of the Sub-Process.

Semantics of the End Event include:

- There MAY be multiple End Events within a single level of a Process.

- An End Event is OPTIONAL: a given Process level—a top-level Process or an expanded Sub-Process—MAY (is not required to) have this shape:
  o If an End Event is not used, then the implicit End Event for the Process SHALL NOT have a Result.
  o If there is a Start Event, then there MUST be at least one End Event.
  o If an End Event is used, then there MUST NOT be other flow elements that do not have any outgoing Sequence Flow—all other Flow Objects MUST be a source of at least one Sequence
Flow.

- Exceptions to this are Activities that are defined as being Compensation Activities (have the Compensation marker). Compensation Activities MUST NOT have any outgoing Sequence Flow, even if there is an End Event in the Process level. See page §14 for more information on Compensation Activities.
  - If the End Event is not used, then all Flow Objects that do not have any outgoing Sequence Flow (i.e., are not a source of a Sequence Flow) mark the end of a path in the Process. However, the Process MUST NOT end until all parallel paths have completed.
  - Exceptions to this are Activities that are defined as being Compensation Activities (have the Compensation marker). Compensation Activities are not considered a part of the normal flow and MUST NOT mark the end of the Process.

Note – A Process may have more than one Process level (i.e., it can include Expanded Sub-Processes). The use of Start and End Events is independent for each level of the Diagram.

For Processes without an End Event, a token entering a path-ending Flow Object will be consumed when the processing performed by the object is completed (i.e., when the path has completed), as if the token had then gone on to reach an End Event. When all tokens for a given instance of the Process are consumed, then the Process will reach a state of being completed.

**End Event Results**

There are nine (9) types of End Events in BPMN: None, Message, Escalation, Error, Cancel, Compensation, Signal, Terminate, and Multiple. These types define the consequence of reaching an End Event. This will be referred to as the End Event Result.

**Table 10-81 – End Event Types**

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The None End Event does not have a defined result. There is no specific EventDefinition subclass (see page 266) for None End Events. If the End Event has no associated EventDefinition, then the Event will be displayed without a marker (see the figure on the right).</td>
<td></td>
</tr>
<tr>
<td>Message</td>
<td>This type of End indicates that a Message is sent to a Participant at the conclusion of the Process. See page 112 for more details on Messages. The actual Participant from which the Message is received can be identified by connecting the Event to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10-1.</td>
<td></td>
</tr>
<tr>
<td>Error</td>
<td>This type of End indicates that a named Error should be generated. All currently active threads in the particular Sub-Process are terminated as a result. The Error will be caught by a Catch Error Intermediate Event with the same errorCode or no errorCode which is on the boundary of the nearest enclosing parent activity (hierarchically). The behavior of the</td>
<td></td>
</tr>
</tbody>
</table>
Process is unspecified if no Activity in the hierarchy has such an Error Intermediate Event. The system executing the process may define additional Error handling in this case, a common one being termination of the Process instance.

**Escalation**

This type of End indicates that an Escalation should be triggered. Other active threads are not affected by this and continue to be executed. The Escalation will be caught by a Catch Escalation Intermediate Event with the same escalationCode or no escalationCode which is on the boundary of the nearest enclosing parent activity (hierarchically). The behavior of the process is unspecified if no activity in the hierarchy has such an Escalation Intermediate Event.

**Cancel**

This type of End is used within a Transaction Sub-Process. It will indicate that the Transaction should be cancelled and will trigger a Cancel Intermediate Event attached to the Sub-Process boundary. In addition, it will indicate that a Transaction Protocol Cancel message should be sent to any Entities involved in the Transaction.

**Compensation**

This type of End indicates that compensation is necessary. If an Activity is identified, and it was successfully completed, then that Activity will be compensated. The Activity must be visible from the Compensation End Event, i.e., one of the following must be true:

- The Compensation End Event is contained in normal flow at the same level of Sub-Process.
- The Compensation End Event is contained in a Compensation Event Sub-Process which is contained in the Sub-Process containing the Activity.

If no Activity is identified, all successfully completed Activities visible from the Compensation End Event are compensated, in reverse order of their Sequence Flow. Visible means one of the following:

- The Compensation End Event is contained in normal flow and at the same level of Sub-Process as the Activities.
- The Compensation End Event is contained in a Compensation Event Sub-Process which is contained in the Sub-Process containing the Activities.

To be compensated, an Activity MUST have a boundary Compensation Event or contain a Compensation Event Sub-Process.

**Signal**

This type of End indicates that a Signal will be broadcasted when the End has been reached. Note that the Signal, which is broadcast to any Process that can receive the Signal, can be sent across Process levels or Pools, but is not a Message (which has a specific Source and Target). The attributes of a Signal can be found on page 282.
**Terminate**

This type of End indicates that all activities in the Process should be immediately ended. This includes all instances of Multi-Instances. The Process is ended without compensation or event handling.

**Multiple**

This means that there are multiple consequences of ending the Process. All of them will occur (e.g., there might be multiple messages sent).

There is no specific EventDefinition subclass (see page 266) for Multiple End Events. If the End Event has more than one associated EventDefinition, then the Event will be displayed with the Multiple Event marker (a pentagon—see the figure on the right).

### Sequence Flow Connections

See Section “Sequence Flow Connections Rules” on page 64 for the entire set of objects and how they may be source or targets of Sequence Flow.

- An End Event MUST be a target for Sequence Flow.
- An End Event MAY have multiple incoming Sequence Flow.

The Flow MAY come from either alternative or parallel paths. For modeling convenience, each path MAY connect to a separate End Event object. The End Event is used as a Sink for all tokens that arrive at the Event. All tokens that are generated at the Start Event for that Process must eventually arrive at an End Event. The Process will be in a running state until all tokens are consumed.

- An End Event MUST NOT be a source for Sequence Flow; that is, there MUST NOT be outgoing Sequence Flow.
  - An exception to this is when an End Event is used in an Expanded Sub-Process and is attached to the boundary of that Sub-Process. In this case, a Sequence Flow from the higher-level Process MAY connect from that End Event in lieu of connecting from the actual boundary of the Sub-Process (see [-->REF]).

### Message Flow Connections

See Section “Message Flow Connection Rules” on page 65 for the entire set of objects and how they may be source or targets of Message Flow.

**Note** – All Message Flow must connect two separate Pools. They can connect to the Pool boundary or to Flow Objects within the Pool boundary. They cannot connect two objects within the same Pool.

- An End Event MUST NOT be the target for Message Flow; it can have no incoming Message Flow. If the Intermediate Event has an incoming Message Flow, then it MUST NOT have an outgoing Message Flow.
- An Intermediate Event of type Message, if it is used within normal flow, MAY be the source for Message Flow; it can have one outgoing Message Flow. If the Intermediate Event has an outgoing Message Flow, then it MUST NOT have an incoming Message Flow.
10.4.4. Intermediate Event

As the name implies, the Intermediate Event indicates where something happens (an Event) somewhere between the start and end of a Process. It will affect the flow of the Process, but will not start or (directly) terminate the Process. Intermediate Events can be used to:

- Show where Messages are expected or sent within the Process,
- Show delays are expected within the Process,
- Disrupt the normal flow through exception handling, or
- Show the extra work required for compensation.

The Intermediate Event shares the same basic shape of the Start Event and End Event, a circle with an open center so that markers can be placed within the circle to indicate variations of the Event.

- An Intermediate Event is a circle that MUST be drawn with a double thin line. (see Figure 10-68).
  - The use of text, color, size, and lines for an Intermediate Event MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63 with the exception that:
    - The thickness of the line MUST remain double so that the Intermediate Event may be distinguished from the Start and End Events.

Figure 10-68 – Intermediate Event

One use of Intermediate Events is to represent exception or compensation handling. This will be shown by placing the Intermediate Event on the boundary of a Task or Sub-Process (either collapsed or expanded). The Intermediate Event can be attached to any location of the Activity boundary and the outgoing Sequence Flow can flow in any direction. However, in the interest of clarity of the Diagram, we recommend that the modeler choose a consistent location on the boundary. For example, if the Diagram orientation is horizontal, then the Intermediate Events can be attached to the bottom of the Activity and the Sequence Flow directed down, then to the right. If the Diagram orientation is vertical, then the Intermediate Events can be attached to the left or right side of the Activity and the Sequence Flow directed to the left or right, then down.

Intermediate Event Triggers

There are twelve (12) types of Intermediate Events in BPMN: None, Message, Timer, Escalation, Error, Cancel, Compensation, Conditional, Link, Signal, Multiple, and Parallel Multiple. Each type of Intermediate Event will have a different icon placed in the center of the Intermediate Event shape to distinguish one from another.

There are two (2) ways that Intermediate Events are used in BPMN:

An Intermediate Event that is placed within the normal flow of a Process can be used for one of two purposes. The Event can respond to (“catch”) the Event Trigger or the Event can be used to set off (“throw”)
the Event Trigger. An Intermediate Event that is attached to the boundary of an Activity can only be used to “catch” the Event Trigger.

Intermediate Events in Normal Flow

When a token arrives at an Intermediate Event that is placed within the normal flow of a Process, one of two things will happen. If the Event is used to “throw” the Event Trigger, then Trigger of the Event will immediately occur (e.g., the Message will be sent) and the token will move down the outgoing Sequence Flow. If the Event is used to “catch” the Event Trigger, then the token will remain at the Event until the Trigger occurs (e.g., the Message is received). Then the token will move down the outgoing Sequence Flow.

Nine (9) of the eleven (11) Intermediate Events can be used in Normal Flow. Table 10-82

Table 10-82 – Intermediate Event Types in Normal Flow

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The None Intermediate Event is only valid in Normal Flow, i.e. it may not be used on the boundary of an Activity. Although there is no specific trigger for this Event, it is defined as throw Event. It is used for modeling methodologies that use Events to indicate some change of state in the Process. There is no specific EventDefinition subclass (see page 266) for None Intermediate Events. If the (throw) Intermediate Event has no associated EventDefinition, then the Event MUST be displayed without a marker (see the figure on the right).</td>
<td>Throw</td>
</tr>
<tr>
<td>Message</td>
<td>A Message Intermediate Event can be used to either send a Message or receive a Message. When used to “throw” the message, the Event marker MUST be filled (see the upper figure on the right). When used to “catch” the message, then the Event marker MUST be unfilled (see the lower figure on the right). This causes the Process to continue if it was waiting for the message, or changes the flow for exception handling. The actual Participant from which the Message is received can be identified by connecting the Event to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10-1. See page 112 for more details on Messages.</td>
<td>Throw, Catch</td>
</tr>
<tr>
<td>Timer</td>
<td>In Normal Flow the Timer Intermediate Event acts as a delay mechanism based on a specific time-date or a specific cycle (e.g., every Monday at 9am) can be set that will trigger the Event. This Event MUST be displayed with a clock marker (see the figure on the right).</td>
<td>Catch</td>
</tr>
<tr>
<td>Escalation</td>
<td>In Normal Flow, the Escalation Intermediate Event raises an Escalation. Since this is a Throw Event, the arrowhead marker will be filled (see the figure to the right).</td>
<td></td>
</tr>
<tr>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
</tbody>
</table>
| Compensation | In normal flow, this Intermediate Event indicates that compensation is necessary. Thus, it is used to “throw” the Compensation Event, and the Event marker MUST be filled (see figure on the right). If an Activity is identified, and it was successfully completed, then that Activity will be compensated. The activity must be visible from the Compensation Intermediate Event, i.e., one of the following must be true:  
  • The Compensation Intermediate Event is contained in normal flow at the same level of Sub-Process.  
  • The Compensation Intermediate Event is contained in a Compensation Event Sub-Process which is contained in the Sub-Process containing the Activity.  
If no Activity is identified, all successfully completed Activities visible from the Compensation Intermediate Event are compensated, in reverse order of their Sequence Flow. Visible means one of the following:  
  • The Compensation Intermediate Event is contained in normal flow and at the same level of Sub-Process as the Activities.  
  • The Compensation Intermediate Event is contained in a Compensation Event Sub-Process which is contained in the Sub-Process containing the Activities.  
To be compensated, an Activity MUST have a boundary Compensation Event, or contain a Compensation Event Sub-Process. |
| Conditional | This type of event is triggered when a Condition becomes true. A Condition is a type of Expression. The attributes of an Expression can be found page 106 |
| Link | The Link Intermediate Events are only valid in Normal Flow, i.e. they may not be used on the boundary of an Activity. A Link is a mechanism for connecting two sections of a Process. Link Events can be used to create looping situations or to avoid long Sequence Flow lines. Link Event uses are limited to a single Process level (i.e., they cannot link a parent Process with a Sub-Process). Paired Intermediate Events can also be used as “Off-Page Connectors” for printing a Process across multiple pages. They can also be used as generic “Go To” objects within the Process level. There can be multiple Source Link Events, but there can only be one Target Link Event.  
When used to “throw” to the Target Link, the Event marker will be filled (see the top figure on the right). When used to “catch” from the Source Link, the Event marker will be unfilled (see the bottom figure on the right). |
<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
<th>Diagram</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signal</td>
<td>This type of event is used for sending or receiving Signals. A Signal is for general communication within and across Process Levels, across Pools, and between Business Process Diagrams. A BPMN Signal is similar to a signal flare that shot into the sky for anyone who might be interested to notice and then react. Thus, there is a source of the Signal, but no specific intended target. This type of Intermediate Event can send or receive a Signal if the Event is part of a Normal Flow. The Event can only receive a Signal when attached to the boundary of an activity. The Signal Event differs from an Error Event in that the Signal defines a more general, non-error condition for interrupting activities (such as the successful completion of another activity) as well as having a larger scope than Error Events. When used to “catch” the signal, the Event marker will be unfilled (see the middle figure on the right). When used to “throw” the signal, the Event marker will be filled (see the top figure on the right). The attributes of a Signal can be found on page 280.</td>
<td></td>
</tr>
<tr>
<td>Multiple</td>
<td>This means that there are multiple Triggers assigned to the Event. If used within normal flow, the Event can “catch” the Trigger or “throw” the Triggers. When attached to the boundary of an activity, the Event can only “catch” the Trigger. When used to “catch” the Trigger, only one of the assigned Triggers is required and the Event marker will be unfilled (see the middle figure on the right). When used to “throw” the Trigger (the same as a Multiple End Event), all the assigned Triggers will be thrown and the Event marker will be filled (see the top figure on the right). There is no specific EventDefinition subclass (see page 266) for Multiple Intermediate Events. If the Intermediate Event has more than one associated EventDefinition, then the Event will be displayed with the Multiple Event marker.</td>
<td></td>
</tr>
<tr>
<td>Parallel Multiple</td>
<td>This means that there are multiple triggers assigned to the Event. If used within normal flow, the Event can only “catch” the trigger. When attached to the boundary of an activity, the Event can only “catch” the trigger. Unlike the normal Multiple Intermediate Event, all of the assigned triggers are required for the Event to be triggered. The Event marker will be an unfilled plus sign (see the figure on the right). There is no specific EventDefinition subclass (see page 266) for Parallel Multiple Intermediate Events. If the Intermediate Event has more than one associated EventDefinition and the parallelMultiple attribute of the Intermediate Event is true, then the Event will be displayed with the Parallel Multiple Event marker.</td>
<td></td>
</tr>
</tbody>
</table>

**Intermediate Events Attached to an Activity Boundary**

Table 10-83 describes the Intermediate Events that can be attached to the boundary of an Activity.
Table 10-83 – Intermediate Event Types Attached to an Activity Boundary

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message</td>
<td>A Message arrives from a participant and triggers the Event. If a Message Event is attached to the boundary of an Activity, it will change the <em>Normal Flow</em> into an <em>Exception Flow</em> upon being triggered. For a Message Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to <em>true</em>. For a Message Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to <em>false</em>. The actual <em>Participant</em> from which the Message is received can be identified by connecting the Event to a <em>Participant</em> using a Message Flow within the definitional Collaboration of the Process – see <a href="#">Table 10-1</a>.</td>
<td></td>
</tr>
<tr>
<td>Timer</td>
<td>A specific time-date or a specific cycle (e.g., every Monday at 9am) can be set that will trigger the Event. If a Timer Event is attached to the boundary of an Activity, it will change the Normal Flow into an Exception Flow upon being triggered. For a Timer Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to <em>true</em>. For a Timer Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to <em>false</em>.</td>
<td></td>
</tr>
<tr>
<td>Event Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
<td></td>
</tr>
<tr>
<td><strong>Escalation</strong></td>
<td>This type of Event is used for handling a named Escalation. If attached to the boundary of an activity, the Intermediate Event <em>catches</em> an Escalation. In contrast to an Error, an Escalation by default is assumed to not abort the activity to which the boundary event is attached. However, a modeler may decide to override this setting by using the notation described in the following. For an Escalation Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to <em>true</em>. For an Escalation Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to <em>false</em>.</td>
<td></td>
</tr>
<tr>
<td><strong>Interrupting</strong></td>
<td><img src="image1" alt="Interrupting" /></td>
<td></td>
</tr>
<tr>
<td><strong>Non-Interrupting</strong></td>
<td><img src="image2" alt="Non-Interrupting" /></td>
<td></td>
</tr>
<tr>
<td><strong>Error</strong></td>
<td>An Intermediate Error Catch Event can only be attached to the boundary of an activity, i.e. it may not be used in Normal Flow. If used in this context, it reacts to (catches) a named error, or to any error if a name is not specified. Note that an Error Event always interrupts the Activity to which it is attached, i.e. there is not a non-interrupting version of this Event. The boundary of the Event thus always solid (see figure on the right).</td>
<td></td>
</tr>
<tr>
<td><strong>Interrupting</strong></td>
<td><img src="image3" alt="Interrupting" /></td>
<td></td>
</tr>
<tr>
<td><strong>Cancel</strong></td>
<td>This type of Intermediate Event is used within a Transaction Sub-Process. This type of Event MUST be attached to the boundary of a Sub-Process. It SHALL be triggered if a Cancel End Event is reached within the Transaction Sub-Process. It also SHALL be triggered if a Transaction Protocol “Cancel” message has been received while the Transaction is being performed. Note that a Cancel Event always interrupts the Activity to which it is attached, i.e. there is not a non-interrupting version of this Event. The boundary of the Event thus always solid (see figure on the right).</td>
<td></td>
</tr>
<tr>
<td><strong>Interrupting</strong></td>
<td><img src="image4" alt="Interrupting" /></td>
<td></td>
</tr>
<tr>
<td><strong>Compensation</strong></td>
<td>When attached to the boundary of an Activity, this Event is used to “catch” the Compensation Event, thus the Event marker MUST be unfilled (see figure on the right). The Event will be triggered by a thrown compensation targeting that Activity. When the Event is triggered, the Compensation Activity that is Associated to the Event will be performed (see page 314). Note that the interrupting a non-interrupting aspect of other Events does not apply in the case of a Compensation Event. Compensations can only be triggered after completion of the activity to which they are attached. Thus they cannot interrupt the Activity. The boundary of the Event is always solid.</td>
<td></td>
</tr>
<tr>
<td><strong>Compensation</strong></td>
<td><img src="image5" alt="Compensation" /></td>
<td></td>
</tr>
</tbody>
</table>
### Conditional

This type of event is triggered when a *Condition* becomes true. A *Condition* is a type of *Expression*. The attributes of an *Expression* can be found on page 106. If a Conditional Event is attached to the boundary of an Activity, it will change the *normal flow* into an *exception flow* upon being triggered.

For a Conditional Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to *true*.

For a Conditional Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to *false*.

### Signal

The Signal Event can only receive a Signal when attached to the boundary of an activity. In this context, it will change the Normal Flow into an Exception Flow upon being triggered. The Signal Event differs from an Error Event in that the Signal defines a more general, non-error condition for interrupting activities (such as the successful completion of another activity) as well as having a larger scope than Error Events. When used to "catch" the signal, the Event marker will be unfilled. The attributes of a Signal can be found on page 280.

For a Signal Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to *true*.

For a Signal Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to *false*.
**Multiple**

A Multiple Event indicates that there are multiple Triggers assigned to the Event. When attached to the boundary of an activity, the Event can only "catch" the Trigger. In this case, only one of the assigned Triggers is required and the Event marker will be unfilled. Upon being triggered, the Event that occurred will change the Normal Flow into an Exception Flow. There is no specific EventDefinition subclass (see page 266) for Multiple Intermediate Events. If the Intermediate Event has more than one associated EventDefinition, then the Event will be displayed with the Multiple Event marker.

For a Multiple Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to *true*.

For a Multiple Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to *false*.

<table>
<thead>
<tr>
<th><strong>Interrupting</strong></th>
<th><strong>Non-Interrupting</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1" alt="Interrupting" /></td>
<td><img src="image2" alt="Non-Interrupting" /></td>
</tr>
</tbody>
</table>

| **Parallel Multiple** | This means that there are multiple triggers assigned to the Event. When attached to the boundary of an activity, the Event can only "catch" the trigger.  
Unlike the normal Multiple Intermediate Event, all of the assigned triggers are required for the Event to be triggered.  
The Event marker will be an unfilled plus sign (see the figures on the right).  
There is no specific EventDefinition subclass (see page 266) for Parallel Multiple Intermediate Events. If the Intermediate Event has more than one associated EventDefinition and the parallelMultiple attribute of the Intermediate Event is *true*, then the Event will be displayed with the Parallel Multiple Event marker.  
For a Parallel Multiple Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see the upper figure to the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to *true*.  
For a Parallel Multiple Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see the lower figure to the right). Note that if using this notation, the attribute cancel Activity of the Activity to which the Event is attached is implicitly set to *false*. |

### Attributes for Boundary Events

For boundary Events, the following additional attributes exists:
The **BoundaryEvent** element inherits the attributes and model associations of **CatchEvent** (see Table 8-45). Table 8-47 presents the additional attributes and model associations of the **Boundary Event** element:

**Table 10-84 – Boundary Event attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>attachedTo: Activity</td>
<td>Denotes the Activity that boundary Event is attached to.</td>
</tr>
<tr>
<td>cancelActivity: boolean</td>
<td>Denotes whether the activity should be cancelled or not, i.e., whether the boundary catch event acts as an error or an escalation. If the activity is not cancelled, multiple instances of that handler can run concurrently. This attribute cannot be applied to error events (where it’s always true), or Compensation Events (where it doesn’t apply).</td>
</tr>
</tbody>
</table>

The following table specifies whether the cancel Activity attribute can be set on a boundary Event depending on the **EventDefinition** it catches.

**Table 10-85 – Possible Values of the cancel Activity Attribute**

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Possible Values for the cancel Activity Attribute</th>
</tr>

### Activity Boundary Connections

An Intermediate Event can be attached to the boundary of an Activity under the following conditions:

- (One or more) Intermediate Events MAY be attached directly to the boundary of an Activity.
  - To be attached to the boundary of an Activity, an Intermediate Event MUST be one of the following Triggers (EventDefinition): Message, Timer, Error, Escalation, Cancel, Compensation, Conditional, Signal, Multiple, and Parallel Multiple.
    - An Intermediate Event with a Cancel Trigger MAY be attached to a Sub-Process boundary only if the Transaction attribute of the Sub-Process is set to true.

### Sequence Flow Connections

See Section “Sequence Flow Connections Rules” on page 64 for the entire set of objects and how they may be source or targets of Sequence Flow.

- The Intermediate Events with the following Triggers (EventDefinition) MAY be attached to the boundary of an Activity: Message, Timer, Error, Cancel (only Sub-Process that is a Transaction), Compensation, Conditional, Signal, Multiple, and Parallel Multiple. Thus, the following MUST NOT: None, and Link.
  - If the Intermediate Event is attached to the boundary of an Activity:
    - The Intermediate Event MUST NOT be a target for Sequence Flow; it cannot have an incoming Flow.
    - The Intermediate Event MUST be a source for Sequence Flow.
    - Multiple Sequence Flow MAY originate from an Intermediate Event. For each Sequence Flow that has the Intermediate Event as a source, a new parallel path SHALL be generated.
      - An exception to this: an Intermediate Event with a Compensation Trigger MUST NOT have an outgoing Sequence Flow (it MAY have an outgoing Association).

- The Intermediate Events with the following Triggers (EventDefinition) MAY be used in normal flow: None, Message, Timer, Compensation, Conditional, Link, and Signal. Thus, the following MUST NOT: Cancel, Error, Multiple, and Parallel Multiple.
  - If the Intermediate Event is used within normal flow:
    - Intermediate Events MUST be a target of a Sequence Flow.

Note – this is a change from BPMN 1.2 semantics, which allowed some Intermediate Events to not have an incoming Sequence Flow.
An Intermediate Event MAY have multiple incoming Sequence Flow.

Note – If the Event has multiple incoming Sequence Flow, then this is considered uncontrolled flow. This means that when a token arrives from one of the Paths, the Event will be enabled (to catch or throw). It will not wait for the arrival of tokens from the other paths. If another token arrives from the same path or another path, then a separate instance of the Event will be created. If the flow needs to be controlled, then the flow should converge with a Gateway that precedes the Event (see page 295 for more information on Gateways).

- An Intermediate Event MUST be a source for Sequence Flow.

- Multiple Sequence Flow MAY originate from an Intermediate Event. For each Sequence Flow that has the Intermediate Event as a source, a new parallel path SHALL be generated.
  - An exception to this: a source Link Intermediate Event (as defined below), it is not required to have an outgoing Sequence Flow.

- A Link Intermediate Event MUST NOT be both a target and a source of a Sequence Flow.

An exception to this: a source Link Intermediate Event (as defined below), it is not required to have an outgoing Sequence Flow.

To define the use of a Link Intermediate Event as an “Off-Page Connector” or a “Go To” object:

- A Link Intermediate Event MAY be the target (target Link) or a source (source Link) of a Sequence Flow, but MUST NOT be both a target and a source.
  - If there is a source Link, there MUST be a matching target Link (they have the same name).
    - There MAY be multiple source Links for a single target Link.
    - There MUST NOT be multiple target Links for a single source Link.

**Message Flow Connections**

See Section “Message Flow Connection Rules” on page 65 for the entire set of objects and how they may be source or targets of Message Flow.

Note – All Message Flow must connect two separate Pools. They can connect to the Pool boundary or to Flow Objects within the Pool boundary. They cannot connect two objects within the same Pool.

- A Message Intermediate Event MAY be the target for Message Flow; it can have one incoming Message Flow.

- A Message Intermediate Event MAY be a source for Message Flow; it can have one outgoing Message Flow.

- A Message Intermediate Event MAY have an incoming Message Flow or an outgoing Message Flow, but not both.

**10.4.5. Event Definitions**

Event Definitions refers to the Triggers of Catch Events (Start and receive Intermediate Events) and the Results of Throw Events (End Events and send Intermediate Events). The types of Event Definitions are: CancelEventDefinition, CompensationEventDefinition, ConditionalEventDefinition, ErrorEventDefinition, EscalationEventDefinition, MessageEventDefinition, LinkEventDefinition, SignalEventDefinition,

Proposal for:  
Business Process Model and Notation (BPMN), v2.0
TerminateEventDefinition, and TimerEventDefinition (see Table 10-86). A None Event is determined by an Event that does not specify an Event Definition. A Multiple Event is determined by an Event that specifies more than one Event Definition. The different types of Events (Start, End, and Intermediate) utilize a subset of the available types of Event Definitions.

</table>
The following sections will present the attributes common to all Event Definitions and the specific attributes for the Event Definitions that have additional attributes. Note that the Cancel and Terminate Event Definitions do not have additional attributes.

**Event Definition Metamodel**

Figure 10-69 shows the class diagram for the abstract class EventDefinition. When one of the EventDefinition sub-types (e.g., TimerEventDefinition) is defined it is contained in Definitions.

![EventDefinition Class Diagram](image)

**Figure 10-69 – EventDefinition Class Diagram**

The EventDefinition element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to RootElement, but does not contain any additional attributes or model associations.

The ErrorEventDefinition, EscalationEventDefinition and SignalEventDefinition subclasses comprise of attributes to carry data. The data is defined as part of the Events package. The MessageEventDefinition subclass comprises of an attribute that refers to a Message which is defined as part of the Collaboration package.

The following sections will present the sub-types of EventDefinitions.
Cancel Event

Cancel Events are only used in the context of modeling Transaction Sub-Processes (see page 268 for more details on Transactions). There are two (2) variations: a catch Intermediate Event and an End Event (Figure 10-70).

- The catch Cancel Intermediate Event MUST only be attached to the boundary of a Transaction Sub-Process and, thus, MAY NOT be used in Normal Flow.
- The Cancel End Event MUST only be used within a Transaction Sub-Process and, thus, MAY NOT be used in any other type of Sub-Process or Process.

![Figure 10-70 – Cancel Events](image)

The CancelEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to the EventDefinition element (see page 169).

Compensation Event

Compensation Events are used in the context of triggering or handling compensation (see page 214 for more details on compensation). There are four (4) variations: a Start Event, both a catch and throw Intermediate Event, and an End Event (Figure 10-71).

- The Compensation Start Event MAY NOT be used for a top-level Process.
- The Compensation Start Event MAY be used for an Event Sub-Process.
- The catch Compensation Intermediate Event MUST only be attached to the boundary of an Activity and, thus, MAY NOT be used in Normal Flow.
- The throw Compensation Intermediate Event MAY be used in Normal Flow.
- The Compensation End Event MAY be used within any Sub-Process or Process.

![Figure 10-71 – Compensation Events](image)

Figure 10-72 displays the class diagram for the CompensationEventDefinition.
The CompensationEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to the EventDefinition element (see page 69). Table 10-87 presents the additional attributes and model associations of the CompensationEventDefinition element:

**Figure 10-72 – CompensationEventDefinition Class Diagram**
Table 10-87 – CompensationEventDefinition attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
</table>
| activityRef: Activity [0..1] | For a Start Event:  
This Event “catches” the compensation for an Event Sub-Process. No further information is required. The Event Sub-Process will provide the Id necessary to match the Compensation Event with the Event that threw the compensation, or the compensation will have been a broadcast.  
For an End Event:  
The Activity to be compensated MAY be supplied. If an Activity is not supplied, then the compensation is broadcast to all completed Activities in the current Sub-Process (if present), or the entire Process Instance (if at the global level).  
For an Intermediate Event within Normal Flow:  
The Activity to be compensated MAY be supplied. If an Activity is not supplied, then the compensation is broadcast to all completed Activities in the current Sub-Process (if present), or the entire Process Instance (if at the global level). This “throws” the compensation.  
For an Intermediate Event attached to the boundary of an Activity:  
This Event “catches” the compensation. No further information is required. The Activity the Event is attached to will provide the Id necessary to match the Compensation Event with the Event that threw the compensation, or the compensation will have been a broadcast. |
| waitForCompletion: boolean = True | For a throw Compensation Event, this flag determines whether the throw Intermediate Event waits for the triggered compensation to complete (the default), or just triggers the compensation and immediately continues (the BPMN 1.2 behavior). |

Conditional Event

Figure 10-73 displays the class diagram for the ConditionalEventDefinition.

Figure 10-73 – Conditional Events

The ConditionalEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to the EventDefinition element (see page 269). Table 10-88 presents the additional model associations of the ConditionalEventDefinition element:
Table 10-88 – ConditionalEventDefinition model associations

</tbody>
</table>

**Link Event Definition**

A Link Event is a mechanism for connecting two sections of a Process. Link Events can be used to create looping situations or to avoid long Sequence Flow lines. The use of Link Events is limited to a single Process level (i.e., they cannot link a parent Process with a Sub-Process).

**Figure 10-78 – Link Events**

Paired Link Events can also be used as “Off-Page Connectors” for printing a Process across multiple pages. They can also be used as generic “Go To” objects within the Process level. There can be multiple source Link Events, but there can only be one target Link Event. When used to “catch” from the source Link, the Event marker will be unfilled (see the top figure on the right). When used to “throw” to the target Link, the Event marker will be filled (see the bottom figure on the right).

Since Process models often extend beyond the length of one printed page, there is often a concern about showing how Sequence Flow connections extend across the page breaks. One solution that is often employed...
is the use of Off-Page connectors to show where one page leaves off and the other begins. BPMN provides Intermediate Events of type Link for use as Off-Page connectors (see Figure 10-79). Note that the figure shows two different printed pages, not two Pools in one diagram). A pair of Link Events is used. One of the pair is shown at the end of one page. This Event is named and has an incoming Sequence Flow and no outgoing Sequence Flow. The second Link Event is at the beginning of the next page, shares the same name, and has an outgoing Sequence Flow and no incoming Sequence Flow.

![Figure 10-79 – Link Events Used as Off-Page Connector](image)

Another way that Link Events can be used is as “Go To” objects. Functionally, they would work the same as for Off-Page Connectors (described above), except that they could be used anywhere in the diagram—on the same page or across multiple pages. The general idea is that they provide a mechanism for reducing the length of Sequence Flow lines. Some modelers may consider long lines as being hard to follow or trace. Go To Objects can be used to avoid very long Sequence Flow (see Figure 10-80 and Figure 10-81). Both diagrams will behave equivalently. For Figure 10-81, if the “Order Rejected” path is taken from the Decision, then the token traversing the Sequence Flow would reach the source Link Event and then “jump” to the target Link Event and continue down the Sequence Flow. The Process would continue as if the Sequence Flow had directly connected the two objects.
Some methodologies prefer that all Sequence Flow only move in one direction; that is, forward in time. These methodologies do not allow Sequence Flow to connect directly to upstream objects. Some consistency in modeling can be gained by such a methodology, but situations that require looping become a challenge. Link Events can be used to make upstream connections and create loops without violating the Sequence Flow direction restriction (see Figure 10-82).

Figure 10-80 – Process with Long Sequence Flow

Figure 10-81 – Process with Link Intermediate Events Used as Go To Objects

Figure 10-82 – Link Events Used for looping
The LinkEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to the EventDefinition element (see page 269). Table 10-91 presents the additional attributes of the LinkEventDefinition element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>If the Trigger is a Link, then the name MUST be entered.</td>
</tr>
</tbody>
</table>

Message Event Definition

Figure 10-83 – MessageEventDefinition Class Diagram

Figure 10-84

Figure 10-84 – Message Events

The MessageEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to the EventDefinition element (see page 269). Table 10-92 presents the additional model associations of the MessageEventDefinition element:
Table 10-92 – MessageEventDefinition model associations

<table>
<thead>
<tr>

<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageRef: Message [0..1]</td>
<td>The Message MUST be supplied (if the processType attribute of the Process is set to executable).</td>
</tr>
<tr>
<td>operationRef: Operation [0..1]</td>
<td>This attribute specifies the operation that is used by the Message Event. It MUST be specified for executable Processes.</td>
</tr>
</tbody>
</table>

Multiple Event

For a Start Event:

If the Trigger is Multiple, there are multiple ways of starting the Process. Only one of them is necessary to trigger the start of the Process. The EventDefinition subclasses will define which Triggers apply.

For an End Event:

If the Result is Multiple, there are multiple consequences of ending the Process. All of them will occur. The EventDefinition subclasses will define which Results apply.

For an Intermediate Event within normal flow:

If the Trigger is Multiple, only one EventDefinition is required to catch the trigger. When used to throw, all of the EventDefinitions are considered and the subclasses will define which Results apply.

For an Intermediate Event attached to the boundary of an Activity:

If the Trigger is Multiple, only one EventDefinition is required to "catch" the trigger.

Figure 10-85 – Multiple Events

None Event

None Events are Events that do not have a defined EventDefinition. There are three (3) variations of None Events: a Start Event, a catch Intermediate Event, and an End Event (see Figure 10-86).

- The None Start Event MAY be used for a top-level Process or any type of Sub-Process (except an Event Sub-Process)
- The None Start Event MAY NOT be used for an Event Sub-Process.
- The catch None Intermediate Event MUST only be used in Normal Flow and, thus, MAY NOT be attached to the boundary of an Activity.
- The None End Event MAY be used within any Sub-Process or Process.

![None Events](image)

**Figure 10-86 – None Events**

**Parallel Multiple Event**

For a Start Event:

If the trigger is Multiple, there are multiple triggers required to start the Process. All of them are necessary to trigger the start of the Process. The EventDefinition subclasses will define which triggers apply. In addition, the parallelMultiple attribute of the Start Event MUST be set to true.

For an Intermediate Event within normal flow:

If the trigger is Multiple, all of the defined EventDefinitions are required to trigger the Event. In addition, the parallelMultiple attribute of the Intermediate Event MUST be set to true.

For an Intermediate Event attached to the boundary of an Activity:

If the trigger is Multiple, all of the defined EventDefinitions are required to trigger the Event. In addition, the parallelMultiple attribute of the Intermediate Event MUST be set to true.

![Parallel Multiple Events](image)

**Figure 10-85** shows the variations of Parallel Multiple Events.

![Multiple Events](image)

**Figure 10-87 – Multiple Events**
Signal Event

The `SignalEventDefinition` element inherits the attributes and model associations of `BaseElement` (see Table 8-5) through its relationship to the `EventDefinition` element (see page 269). Table 10-93 presents the additional model associations of the `ConditionalSignalDefinition` element:

**Table 10-93 – SignalEventDefinition model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>signalRef: Signal</td>
<td>If the Trigger is a Signal, then a Signal is provided</td>
</tr>
</tbody>
</table>

Terminate Event

Figure 10-90
Figure 10-90 – Terminate Event

The CancelEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to the EventDefinition element (see page 269).

**Timer Event**

Figure 10-91

Figure 10-91 – Timer Events

The TimerEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8-5) through its relationship to the EventDefinition element (see page 269). Table 10-94 presents the additional model associations of the TimerEventDefinition element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeDate: Expression [0..1]</td>
<td>If the Trigger is a Timer, then a timeDate MAY be entered. If a timeDate is not entered, then a timeCycle MUST be entered (see attribute below—if the processType attribute of the Process is set to executable).</td>
</tr>
<tr>
<td>timeCycle: Expression [0..1]</td>
<td>If the Trigger is a Timer, then a timeCycle MAY be entered. If a timeCycle is not entered, then a timeDate MUST be entered (see attribute above—if the processType attribute of the Process is set to executable).</td>
</tr>
</tbody>
</table>

10.4.6. Handling Events

BPMN provides advanced constructs for dealing with Events that occur during the execution of a Process (i.e., the “catching” of an Event). Furthermore, BPMN supports the explicit creation of an Event in the Process (i.e., the “throwing” of an Event). Both catching and throwing of an Event as well as the resulting Process behavior is referred to as Event handling. There are three (3) types of Event handlers: those that start a Process, those that are part of the normal Sequence Flow, and those that are attached to Activities, either via boundary Events or via separate inline handlers in case of an Event Sub-Process.
Handling Start Events

There are multiple ways in which a Process can be started. For single Start Events, handling consists of starting a new Process instance each time the Event occurs. Sequence Flow leaving the Event is then followed as usual. For multiple Start Events, BPMN supports several modeling scenarios that can be applied depending on the scenario.

**Exclusive start:** the most common scenario for starting a Process is its instantiation by exactly one out of many possible Start Events. Each occurrence of one of these Events will lead to the creation of a new Process instance. The following example shows two Events connected to a single Activity (see Figure 10-92). At runtime, each occurrence of one of the Events will lead to the creation of a new instance of the Process instance and activation of the Activity. Note that a single Multiple Start Event that contains the Message Event Definitions would behave in the same way.

![Figure 10-92 – Exclusive start of a Process](image)

A Process can also be started via an Event-Based Gateway, as in the following example:

![Figure 10-93 – A Process initiated by an Event-Based Gateway](image)

In that case, the first matching Event will create a new instance of the Process, and waiting for the other Events originating from the same decision stops, following the usual semantics of the Event-Based
Exclusive Gateway. Note that this is the only scenario where a Gateway can exist without an incoming Sequence Flow.

It is possible to have multiple groups of Event-Based Gateways starting a Process, provided they participate in the same Conversation and hence share the same correlation information. In that case, one Event out of each group needs to arrive; the first one creates a new Process instance, while the subsequent ones are routed to the existing instance, which is identified through its correlation information.

Event synchronization: if the modeler requires several disjoint Start Events to be merged into a single Process instance, then the following notation must be applied:

![Activity](example.png)

Figure 10-94 – Event synchronization at Process start

The Parallel Start Event may group several disjoint Start Events each of which must occur once in order for an Instance of the Process to be created. Sequence Flow leaving the Event is then followed as usual.

See page 442 for the execution semantics for the Event Handling of Start Events.

Handling Events within normal Sequence Flow (Intermediate Events)

For Intermediate Events, the handling consists of waiting for the Event to occur. Waiting starts when the Intermediate Event is reached. Once the Event occurs, it is consumed. Sequence flow leaving the Event is followed as usual.

Handling Events attached to an Activity (Intermediate boundary Events and Event Sub-Processes)

For boundary Events, handling consists of consuming the Event occurrence and either canceling the Activity the Event is attached to, followed by normal Sequence Flow leaving that Activity, or by running an Event Handler without canceling the Activity (only for Message, Signal, Timer and Conditional Events, not for Error Events).

An interrupting boundary Event is defined by a true value of its cancelActivity attribute. Whenever the Event occurs, the associated Activity is terminated. A downstream token is then generated, which activates the next element of the Process (connected to the Event by an unconditional Sequence Flow called an Exception Flow).

For non-interrupting boundary Events, the cancelActivity attribute is set to false. Whenever the Event occurs, the associated Activity continues to be active. As a token is generated for the Sequence Flow from the boundary Event in parallel to the continuing execution of the Activity, care must be taken when this flow is merged into the main flow of the Process – typically it should be ended with its own End Event.

The following example shows a fragment (see Figure 10-95) from a trip booking Process. It contains a Sub-Process that consists of a main part, and three Event Sub-Processes to deal with Events within the...
same context: an error Event Sub-Process that cancels the Sub-Process, a Message Event Sub-Process that updates the state of the Sub-Process while allowing it to continue, and a Compensation Event Sub-Process (see page 188).

Figure 10-95 – Example of inline Event Handling via Event Sub-Processes

The following example (see Figure 10-96) shows the same fragment of that Process, using boundary Event handlers rather than inline Event Sub-Processes. Note that in this example, the handlers do not have access to the context of the “Booking” Sub-Process, as they run outside of it. Therefore, the actually compensation logic is shown as a black box.
Figure 10-96 – Example of boundary Event Handling

Note that there is a distinction between interrupting and non-interrupting Events and the handling of these Events, which is described in the sections below. For an interrupting Event (Error, Escalation, Message, Signal, Timer, Conditional, Multiple, and Parallel Multiple), only one Event Sub-Process for the same Event Declaration may be modeled. This excludes any further non-interrupting handlers for that Event Declaration.

The reason for this restriction lies in the nature of interrupting Event Sub-Processes and boundary Events. They execute synchronously and after their completion, the hosting Activity is immediately terminated. This implies that only one such handler can be executed at a time. However, this does not restrict the modeler in specifying several interrupting handlers, if each handler refers to a different Event Declaration.

For non-interrupting Events (Escalation, Message, Signal, Timer, Conditional, Multiple, and Parallel Multiple), an unlimited number of Event Sub-Processes for the same Event Declaration can be modeled and executed in parallel. At runtime, they will be invoked in a non-deterministic order. The same restrictions apply for boundary Events.

If for a given Sub-Process, both an inline Event Sub-Process and a boundary Event handler are modeled that Process the same EventDefinition, the following semantics apply:

- If the inline Event Sub-Process “rethrows” the Event after completion, the boundary Event is triggered
- If the inline Event Sub-Process completes without “rethrowing” the Event, the Activity is considered to have completed and normal Sequence Flow resumes. In other terms, the Event Sub-Process “absorbs” the Event.
Interrupting Event Handlers (Error, Escalation, Message, Signal, Timer, Conditional, Multiple, and Parallel Multiple)

Interrupting Event Handlers are those that have the cancelActivity attribute set to true. Whenever the Event occurs, regardless of whether the Event is handled inline or on the boundary, the associated Activity is canceled. If an inline error handler is specified (in case of a Sub-Process), it is run within the context of that Sub-Process. If a boundary Error Event is present, Sequence Flow from that boundary Event is then followed.

In the example above, the “Booking” Sub-Process has an Error handler that defines what should happen in case a “Booking” Error occurs within the Sub-Process, namely, the already performed bookings are canceled using compensation. The Error handler is then continued outside the Sub-Process through a boundary Error Event.

Non-interrupting Event Handlers (Escalation, Message, Signal, Timer, Conditional, Multiple, and Parallel Multiple)

Interrupting Event Handlers are those that have the cancelActivity attribute set to false.

For Event Sub-Processes, whenever the Event occurs it is consumed and the associated Event Sub-Process is performed. If there are several Events that happen in parallel, then they are handled concurrently, i.e., several Event Sub-Process instances are created concurrently. The non-interrupting Start Event indicates that the Event Sub-Process instance runs concurrently to the Sub-Process proper.

For boundary Events, whenever the Event occurs the handler runs concurrently to the Activity. If an Event Sub-Process is also specified for that Event (in case of a Sub-Process), it is run within the context of that Sub-Process. Then, Sequence Flow from the boundary Event is followed. As a token is generated for the Sequence Flow from the boundary Event in parallel to the continuing execution of the Activity, care must be taken when this flow is merged into the main flow of the Process – typically it should be ended with its own End Event.

In the example above, an Event Handler allows to update the credit card information during the “Booking” Sub-Process. It is triggered by a credit card information Message: such a Message can be received whenever the control flow is within the main body of the Sub-Process. Once such a Message is received, the Activities within the corresponding Event Handler run concurrently with the Activities within the body of the Sub-Process.

See page 442 for the exact semantics of boundary Intermediate Events and page 443 for the operational semantics of non-interrupting Event Sub-Processes.

Handling End Events

For a Terminate End Event, all remaining active Activities within the Process are terminated.

A Cancel End Event is only allowed in the context of a Transaction Sub-Process and, as such, cancels the Sub-Process and aborts an associated Transaction of the Sub-Process.
For all other End Events, the behavior associated with the EventDefinition is performed. When there are no further active Activities, then the Sub-Process or Process instance is completed. See page 43 for exact semantics.

### 10.4.7. Scopes

A scope describes the context in which execution of an Activity happens. This consists of:

- The set of Data Objects available (including DataInput and DataOutput)
- The set of Events available for catching or throwing triggers
- The set of Conversations going on in that scope

In general, a scope contains exactly one main flow of Activities which is started, when the scope gets activated. Vice versa, all Activities are enclosed by a scope. Scopes are hierarchically nested.

Scopes may have several scope instances at runtime. They are also hierarchically nested according to their generation. In a scope instance several tokens may be active.

Scope instances in turn have a lifecycle, containing amongst others the states:

- Activated
- In execution
- Completed
- In Compensation
- Compensation
- In Error
- In Cancellation
- Cancelled

BPMN has the following model elements with scope characteristics:

- Choreography
- Pool
- Sub-Process
- Task
- Activity
- Multi-instances body

Scopes are used to define the semantics of

- Visibility of Data Objects (including DataInput and DataOutput)
- Event resolution
- Starting/stopping of token execution
The Data Objects, Events and correlation keys described by a scope may be explicitly modeled or implicitly defined.

### 10.4.8. Events Package XML Schemas

#### Table 10-95 – BoundaryEvent XML schema
```
<xs:element name="boundaryEvent" type="tBoundaryEvent" substitutionGroup="flowElement"/>
<xs:complexType name="tBoundaryEvent">

                <xsd:element ref="eventDefinitionRef" type="xsd:QName" minOccurs="0" maxOccurs="unbounded"/>
            </xsd:sequence>
        </xsd:extension>
    </xsd:complexContent>
</xsd:complexType>
```
Table 10-115 – TimerEventDefinition XML schema

```xml
<xsd:element name="timerEventDefinition" type="tTimerEventDefinition"
    substitutionGroup="eventDefinition"/>
<xsd:complexType name="tTimerEventDefinition">
    <xsd:complexContent>
        <xsd:extension base="tEventDefinition">
            <xsd:choice>
                <xsd:element name="timeDate" type="tExpression" minOccurs="0" maxOccurs="1"/>
                <xsd:element name="timeCycle" type="tExpression" minOccurs="0" maxOccurs="1"/>
            </xsd:choice>
        </xsd:extension>
    </xsd:complexContent>
</xsd:complexType>
```

10.5. Gateways

Gateways are used to control how Sequence Flows interact as they converge and diverge within a Process. If the flow does not need to be controlled, then a Gateway is not needed. The term “Gateway” implies that there is a gating mechanism that either allows or disallows passage through the Gateway—that is, as Tokens arrive at a Gateway, they can be merged together on input and/or split apart on output as the Gateway mechanisms are invoked.

A Gateway is a diamond, which has been used in many flow chart notations for exclusive branching and is familiar to most modelers.

- A Gateway is a diamond that MUST be drawn with a single thin line (see Figure 10-97).
- The use of text, color, size, and lines for a Gateway MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63 with the exception that:

![Figure 10-97 – A Gateway](image)

Gateways, like Activities, are capable of consuming or generating additional tokens, effectively controlling the execution semantics of a given Process. The main difference is that Gateways do not represent ‘work’ being done and they are considered to have zero effect on the operational measures of the Process being executed (cost, time, etc.).

Gateways can define all the types of Business Process Sequence Flow behavior: Decisions/branching (exclusive, inclusive, and complex), merging, forking, and joining. Thus, while the diamond has been used traditionally for exclusive decisions, BPMN extends the behavior of the diamonds to reflect any type of Sequence Flow control. Each type of Gateway will have an internal indicator or marker to show the type of Gateway that is being used (see Figure 10-98).
The Gateway controls the flow of both diverging and converging Sequence Flow. That is, a single Gateway could have multiple input and multiple output flows. Modelers and modeling tools may want to enforce a best practice of a Gateway only performing one of these functions. Thus, it would take two sequential Gateways to first converge and then to diverge the Sequence Flow.
Figure 10-99 – Gateway class diagram

Gateways are described in this section on an abstract level. The execution semantics of Gateways is detailed on page 436.

10.5.1. Sequence Flow Considerations

Note – Although the shape of a Gateway is a diamond, it is not a requirement that incoming and outgoing Sequence Flow must connect to the corners of the diamond. Sequence Flow can connect to any position on the boundary of the Gateway shape.

This section applies to all Gateways. Additional Sequence Flow Connection rules may be specified for each type of Gateway in the sections below.

- A Gateway MAY be a target for Sequence Flow. It can have zero (0), one (1), or more incoming Sequence Flow.
- If the Gateway does not have an incoming Sequence Flow, and there is no Start Event for the Process, then the Gateway’s divergence behavior, depending on the type of Gateway (see below), SHALL be performed when the Process is instantiated.
- A Gateway MAY be a source of Sequence Flow; it can have zero (0), one (1), or more outgoing Sequence Flow.
- A Gateway MUST have either multiple *incoming* Sequence Flow or multiple *outgoing* Sequence Flow (i.e., it must merge or split the flow).
- A Gateway with a gatewayDirection of unspecified MAY have both multiple *incoming* and *outgoing* Sequence Flow.
- A Gateway with a gatewayDirection of mixed MUST have both multiple *incoming* and *outgoing* Sequence Flow.
- A Gateway with a gatewayDirection of converging MUST have multiple *incoming* Sequence Flow, but MUST NOT have multiple *outgoing* Sequence Flow.
- A Gateway with a gatewayDirection of diverging MUST have multiple *outgoing* Sequence Flow, but MUST NOT have multiple *incoming* Sequence Flow.

10.5.2. Exclusive Gateway

A diverging Exclusive Gateway (Decision) is used to create alternative paths within a Process flow. This is basically the “diversion point in the road” for a Process. For a given *instance* of the Process, only one of the paths can be taken.

A Decision can be thought of as a question that is asked at a particular point in the Process. The question has a defined set of alternative answers. Each question is associated with a condition expression that is associated with a Gateway’s *outgoing* Sequence Flow.

- The Exclusive Gateway MAY use a marker that is shaped like an “X” and is placed within the Gateway diamond (see Figure 10-101) to distinguish it from other Gateways. This marker is not required (see Figure 10-100).
- A diagram SHOULD be consistent in the use of the “X” internal indicator. That is, a diagram SHOULD NOT have some Gateways with an indicator and other Gateways without an indicator.

![Exclusive Gateway Diagram](image)

*Figure 10-100 – An Exclusive Data-Based Decision (Gateway) Example without the Internal Indicator*
Figure 10-101 – A Data-Based Exclusive Decision (Gateway) Example with the Internal Indicator

**Note** – as a modeling preference, the Exclusive Gateways shown in examples within this specification will be shown without the internal indicator.

A default path can optionally be identified, to be taken in the event that none of the conditional expressions evaluate to *true*. If a default path is not specified and the Process is executed such that none of the conditional expressions evaluates to *true*, a runtime exception occurs.

A converging Exclusive Gateway is used to merge alternative paths. Each incoming control flow *token* is routed to the *outgoing* Sequence Flow without synchronization.
The Exclusive Gateway element inherits the attributes and model associations of Gateway (see Table 8-47). Table 10-116 presents the additional attributes and model associations of the Exclusive Gateway element:

**Table 10-116 – ExclusiveGateway Attributes & Model Associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>default</code> : SequenceFlow [0..1]</td>
<td>The Sequence Flow that will receive a Token when none of the conditionExpressions on other outgoing Sequence Flow evaluate to true. The <code>default</code> Sequence Flow should not have a conditionExpression. Any such Expression SHALL be ignored.</td>
</tr>
</tbody>
</table>

### 10.5.3. Inclusive Gateway

A diverging Inclusive Gateway (Inclusive Decision) can be used to create alternative but also parallel paths within a Process flow. Unlike the Exclusive Gateway, all condition expressions are evaluated. The `true` evaluation of one condition expression does not exclude the evaluation of other condition expressions. All Sequence Flow with a `true` evaluation will be traversed by a Token. Since each path is considered to be
independent, all combinations of the paths may be taken, from zero to all. However, it should be designed so that at least one path is taken.

- The Inclusive Gateway MUST use a marker that is in the shape of a circle or an “O” and is placed within the Gateway diamond (see Figure 10-103) to distinguish it from other Gateways.

![Figure 10-103 – An example using an Inclusive Gateway](image)

A default path can optionally be identified, to be taken in the event that none of the conditional expressions evaluate to \textit{true}. If a default path is not specified and the Process is executed such that none of the conditional expressions evaluates to \textit{true}, a runtime exception occurs.

A converging Inclusive Gateway is used to merge a combination of alternative and parallel paths. A control flow Token arriving at an Inclusive Gateway may be synchronized with some other Tokens that arrive later at this Gateway. The precise synchronization behavior of the Inclusive Gateway can be found on page 438.
The Inclusive Gateway element inherits the attributes and model associations of Gateway (see Table 8-47). Table 10-117 presents the additional attributes and model associations of the Inclusive Gateway element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>default: SequenceFlow [0..1]</td>
<td>The Sequence Flow that will receive a Token when none of the conditionExpressions on other Sequence Flow evaluate to true. The default Sequence Flow should not have a conditionExpression. Any such Expression SHALL be ignored.</td>
</tr>
</tbody>
</table>

10.5.4. Parallel Gateway

A Parallel Gateway is used to synchronize (combine) parallel flows and to create parallel flows.

- The Parallel Gateway MUST use a marker that is in the shape of a plus sign and is placed within the Gateway diamond (see Figure 10-105) to distinguish it from other Gateways.
Parallel Gateways are used for synchronizing parallel flow (see Figure 10-106).

A Parallel Gateway creates parallel paths without checking any conditions; each outgoing Sequence Flow receives a token upon execution of this Gateway. For incoming flows, the Parallel Gateway will wait for all incoming flows before triggering the flow through its outgoing Sequence Flows.
The Parallel Gateway element inherits the attributes and model associations of Gateway (see Table 8-47), but adds no additional attributes or model associations.

10.5.5. Complex Gateway

The Complex Gateway can be used to model complex synchronization behavior. An Expression activationCondition is used to describe the precise behavior. For example, this Expression could specify that tokens on three out of five incoming Sequence Flow are needed to activate the Gateway. What tokens are produced by the Gateway is determined by conditions on the outgoing Sequence Flow as in the split behavior of the Inclusive Gateway. If token arrive later on the two remaining Sequence Flow, those tokens cause a reset of the Gateway and new token can be produced on the outgoing Sequence Flow. To determine whether it needs to wait for additional tokens before it can reset, the Gateway uses the synchronization semantics of the Inclusive Gateway.

- The Complex Gateway MUST use a marker that is in the shape of an asterisk and is placed within the Gateway diamond (see Figure 10-108) to distinguish it from other Gateways.

![Figure 10-107 – Parallel Gateway class diagram](image-url)
Figure 10-108 – An example using a Complex Gateway

The Complex Gateway has, in contrast to other Gateways, an internal state, which is represented by the Boolean instance attribute waitingForStart, which is initially true and becomes false after activation. This attribute can be used in the conditions of the outgoing Sequence Flow to specify where tokens are produced upon activation and where tokens are produced upon reset. It is recommended that each outgoing Sequence Flow may either get a token upon activation or upon reset but not both. At least one outgoing Sequence Flow should receive a token upon activation but no token may be produced upon reset.

Figure 10-109 shows the class diagram for the Complex Gateway.
The Complex Gateway element inherits the attributes and model associations of Gateway (see Table 8-47). Table 10-118 presents the additional model associations of the Complex Gateway element:

Table 10-118 – Complex Gateway model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>activationCondition: Expression [0..1]</td>
<td>Determines which combination of incoming tokens will be synchronized for activation of the Gateway.</td>
</tr>

<tr>
<td>activationCount: integer</td>
<td>Refers at runtime to the number of tokens that are present on an incoming Sequence Flow of the Complex Gateway.</td>
</tr>
<tr>
<td>waitingForStart: boolean</td>
<td>Represents the internal state of the Complex Gateway. It is either waiting for start (=true) or waiting for reset (=false).</td>
</tr>
</tbody>
</table>

10.5.6. Event-Based Gateway

The Event-Based Gateway represents a branching point in the Process where the alternative paths that follow the Gateway are based on Events that occur, rather than the evaluation of Expressions using Process data (as with an Exclusive or Inclusive Gateway). A specific Event, usually the receipt of a Message, determines the path that will be taken. Basically, the decision is made by another Participant, based on data that is not visible to Process, thus, requiring the use of the Event-Based Gateway.

For example, if a company is waiting for a response from a customer they will perform one set of Activities if the customer responds “Yes” and another set of Activities if the customer responds “No.” The customer’s response determines which path is taken. The identity of the Message determines which path is taken. That is, the “Yes” Message and the “No” Message are different Messages—i.e., they are not the same Message with different values within a property of the Message. The receipt of the Message can be modeled with an Intermediate Event with a Message Trigger or a Receive Task. In addition to Messages, other Triggers for Intermediate Events can be used, such as Timers.

The Event Gateway shares the same basic shape of the Gateways, a diamond, with a marker placed within the diamond to indicate variations of the Gateway.

- An Event Gateway is a diamond that MUST be drawn with a single thin line.
- The use of text, color, size, and lines for a Start Event MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.
- The marker for the Event Gateway MUST look like a catch Multiple Intermediate Event (see Figure 10-110).

![Figure 10-110 – Event-Based Gateway]

Unlike other Gateways, the behavior of the Event Gateway is determined by a configuration of elements, rather than the single Gateway.

- An Event Gateway MUST have two (2) or more outgoing Sequence Flow.
The outgoing Sequence Flow of the Event Gateway MUST NOT have a conditionExpression.

The objects that are on the target end of the Gateway's outgoing Sequence Flow are part of the configuration of the Gateway.

- Event-Based Gateways are configured by having outgoing Sequence Flow target an Intermediate Event or a Receive Task in any combination (see figures Figure 10-111 and Figure 10-112) except that:
  - If Message Intermediate Events are used in the configuration, then Receive Tasks MUST NOT be used in that configuration and vice versa.
  - Receive Tasks used in an Event Gateway configuration MUST NOT have any attached Intermediate Events.
  - Only the following Intermediate Event triggers are valid: Message, Signal, Timer, Conditional, and Multiple (which can only include the previous triggers). Thus, the following Intermediate Event triggers are not valid: Error, Cancel, Compensation, and Link.
  - Target elements in an Event Gateway configuration MUST NOT have any addition incoming Sequence Flow (other than that from the Event Gateway).

Figure 10-111 – An Event-Based Gateway example using Message Intermediate Events
When the first Event in the Event Gateway configuration is triggered, then the path that follows that Event will used (a token will be sent down the Event’s outgoing Sequence Flow). All the remaining paths of the Event Gateway configuration will no longer be valid. Basically, the Event Gateway configuration is a race condition where the first Event that is triggered wins.

There are variations of the Event Gateway that can be used at the start of the Process. The behavior and marker of the Gateway will change.

Event Gateways can be used to instantiate a Process. By default the Gateway’s instantiate attribute is false, but if set to true, then the Process is instantiated when the first Event of the Gateway’s configuration is triggered.

- If the Event Gateway’s instantiate attribute is set to true, then the marker for the Event Gateway looks like a Multiple Start Event (see Figure 10-113).

In order for an Event Gateway to instantiate a Process, it must meet one of the following conditions:

- The Process does not have a Start Event and the Gateway has no incoming Sequence Flow, or
- The incoming Sequence Flow for the Gateway has a source of a None Start Event.
  - Note that no other incoming Sequence Flow are allowed for the Gateway (in particular, a loop connection from a downstream object).
In some situations a modeler may want the Process to be instantiated by one of a set of Messages while still requiring all of the Messages for the working of the same Process instance. To handle this, there is another variation of the Event Gateway.

- If the Event Gateway’s instantiate attribute is set to true and the eventGatewayType attribute is set to Parallel, then the marker for the Event Gateway looks like a Parallel Multiple Start Event (see Figure 10-114).
- The Event Gateway’s instantiate attribute MUST be set to true in order for the eventGatewayType attribute to be set to Parallel (i.e., for Event Gateway’s that do not instantiate the Process MUST be Exclusive—a standard Parallel Gateway can be used to include parallel Events in the middle of a Process).

Figure 10-114 – Parallel Event-Based Gateway to start a Process

The Parallel Event Gateway is also a type of race condition. In this case, however, when the first Event is triggered and the Process is instantiated, the other Events of the Gateway configuration are not disabled. The other Events are still waiting and are expected to be triggered before the Process can (normally) complete. In this case, The Messages that trigger the Events of the Gateway configuration must share the same correlation information.
The Event-Based Gateway element inherits the attributes and model associations of Gateway (see Table 8-47). Table 10-120 presents the additional attributes and model associations of the Event-Based Gateway element:

Table 10-120 – EventBasedGateway Attributes & Model Associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>instantiate: boolean = False</td>
<td>When true, receipt of one of the events will instantiate the process instance.</td>
</tr>
<tr>
<td>eventGatewayType:</td>
<td>The eventGatewayType determines the behavior of the Gateway when used to instantiate a Process (as described above).</td>
</tr>
<tr>
<td>EventGatewayType =</td>
<td>The attribute can only be set to Parallel when the instantiate attribute is set to true.</td>
</tr>
<tr>
<td>Exclusive</td>
<td></td>
</tr>
</tbody>
</table>
Event-Based Gateways can be used at the start of a Process, without having to be a target of a Sequence Flow. There can be multiple such Event-Based Gateways at the start of a Process. Ordinary Start Events and Event-Based Gateways can be used together.

10.5.7. Gateway Package XML Schemas

Table 10-121 – ComplexGateway XML schema

```xml
<xsd:element name="complexGateway" type="tComplexGateway"
substitutionGroup="flowElement"/>
<xsd:complexType name="tComplexGateway">
  <xsd:complexContent>

    </xsd:complexContent>
</xsd:complexType>
```
10.6. Compensation

Compensation is concerned with undoing steps that were already successfully completed, because their results and possibly side effects are no longer desired and need to be reversed. If an Activity is still active, it cannot be compensated, but rather needs to be canceled. Cancellation in turn may result in compensation of already successfully completed portions of an active Activity, in case of a Sub-Process.

Compensation is performed by a compensation handler. A compensation handler performs the steps necessary to reverse the effects of an Activity. In case of a Sub-Process, the compensation handler has access to Sub-Process data at the time of its completion (“snapshot data”).

Compensation is triggered by a throw Compensation Event, which typically will be raised by an error handler, as part of cancellation, or recursively by another compensation handler. That Event specifies the Activity for which compensation is to be performed, either explicitly or implicitly.

10.6.1. Compensation Handler

A compensation handler is a set of Activities that are not connected to other portions of the BPMN model. The compensation handler starts with a catch Compensation Event. That catch Compensation Event either is a boundary Event, or, in case of a Compensation Event Sub-Process, the handler’s Start Event.

A compensation handler connected via a boundary Event can only perform “black-box” compensation of the original Activity. This compensation is modeled with a specialized Compensation Activity, which is connected to the boundary Event through an Association (see Figure 10-116). The Compensation Activity, which can be either a Task or a Sub-Process, has a marker to show that it is used for compensation only and is outside the normal flow of the Process.

![Figure 10-116 – Compensation through a boundary Event](image)

A Compensation Event Sub-Process is contained within a Process or a Sub-Process (see Figure 10-117). Like the Compensation Activity, the Compensation Event Sub-Process is outside the normal flow of the Process. The Event Sub-Process, which is marked with a dotted line boundary, can access data that is part of its parent, a snapshot at the point in time when its parent completed. A Compensation Event Sub-Process can recursively trigger compensation for Activities contained in its parent.
It is possible to specify that a Sub-Process can be compensated without having to define the compensation handler. The Sub-Process attribute compensable, when set, specifies that default compensation is implicitly defined, which recursively compensates all successfully completed Activities within that Sub-Process.

The example on page 286 contains a custom Compensation Event Sub-Process, triggered by a Compensation Start Event. Note that this compensation handler deviates from default compensation in that it runs Compensation Activities in an order different from the order in the forward case; it also contains an additional Activity adding Process logic that cannot be derived from the body of the Sub-Process itself.

**10.6.2. Compensation Triggering**

Compensation is triggered using a compensation throw Event, which can either be an Intermediate or an End Event. The Activity which needs to be compensated is referenced. If the Activity is clear from the context, it doesn’t have to be specified and defaults to the current Activity. A typical scenario for that is an inline error handler of a Sub-Process that cannot recover the error, and as a result would trigger compensation for that Sub-Process. If no Activity is specified in a “global” context, all completed Activities in the Process are compensated.
By default, compensation is triggered synchronously, that is, the compensation throw Event waits for the completion of the triggered compensation handler. Alternatively, compensation can just be triggered without waiting for its completion, by setting the throw Compensation Event’s waitForCompletion attribute to false.

Multiple instances typically exist for Loop or Multi-Instance Sub-Processes. Each of these has its own instance of its Compensation Event Sub-Process, which has access to the specific snapshot data that was current at the time of completion of that particular instance. Triggering compensation for the Multi-Instance Sub-Process individually triggers compensation for all instances within the current scope. If compensation is specified via a boundary compensation handler, this boundary compensation handler also is invoked once for each instance of the Multi-Instance Sub-Process in the current scope.

### 10.6.3. Relationship between Error Handling and Compensation

The following items define the relationship between error handling and compensation:

- **Compensation** employs a “presumed abort principle”, with the following consequences: Compensation of a failed Activity results in a null operation.
- When an Activity fails, i.e., is left because an error has been thrown, it’s the error handlers responsibility to ensure that no further compensation will be necessary once the error handler has completed.
- If no error Event Sub-Process is specified for a particular Sub-Process and a particular error, the default behavior is to automatically call compensation for all contained Activities of that Sub-Process if that error is thrown, ensuring the behavior in for auditing and monitoring.

### 10.7. Lanes

A Lane is a sub-partition within a Pool or a Process and will extend the entire length of the Diagram, either vertically (see Figure 10-118) or horizontally (see Figure 10-119). If the Process is invisibly bounded, the Lane must extend the entire length of the Process. Text associated with the Lane (e.g., its name and/or that of any Process element attribute) can be placed inside the shape, in any direction or location, depending on the preference of the modeler or modeling tool vendor. Our examples place the name as a banner on the left side (for horizontal Pools) or at the top (for vertical Pools) on the other side of the line that separates the Pool name, however, this is not a requirement.

- A Lane is a square-cornered rectangle that MUST be drawn with a solid single line (see Figure 10-118 and Figure 10-119)
- The label for the Pool MAY be placed in any location and direction within the Pool, but MUST NOT be separated from the contents of the Pool by a single line (except in the case that there are sub-Lanes within the Lane).
Lanes are used to organize and categorize Activities within a Pool. The meaning of the Lanes is up to the modeler. BPMN does not specify the usage of Lanes. Lanes are often used for such things as internal roles (e.g., Manager, Associate), systems (e.g., an enterprise application), an internal department (e.g., shipping, finance), etc. In addition, Lanes can be nested (see Figure 10-120) or defined in a matrix. For example, there could be an outer set of Lanes for company departments and then an inner set of Lanes for roles within each department.
Figure 10-120 – An Example of Nested Lanes

Figure 10-121 shows the Lane class diagram. When a Lane is defined it is contained within a LaneSet, which is contained within a Process.
The LaneSet element defines the container for one or more Lanes. A Process can contain one or more LaneSets. Each LaneSet and its Lanes can partition the Flow Elements in a different way.

The LaneSet element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 10-127 presents the additional attributes and model associations of the LaneSet element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>process: Process</td>
<td>The process owning the LaneSet</td>
</tr>
<tr>
<td>lanes: Lane [0..*]</td>
<td>One or more Lane elements, which define a specific partition in the LaneSet</td>
</tr>
<tr>
<td>parentLane: Lane [0..1]</td>
<td>The reference to a Lane element which is the parent of this LaneSet.</td>
</tr>
</tbody>
</table>

A Lane element defines one specific partition in a LaneSet. The Lane can define a partition element which specifies the value and element type, a tool can use to determine the list of Flow Elements to be partitioned into this Lane. All Lanes in a single LaneSet must define partition element of the same type, e.g. all Lanes in a LaneSet defines the Performer element as the partition element, but all with different values.

The Lane element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 10-128 presents the additional attributes and model associations of the Lane element:
Table 10-28 – Lane attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>The name of the Lane</td>
</tr>
<tr>
<td>partitionElement:</td>
<td>A reference to a BaseElement which specify the partition value and partition type. Using this partition element a BPMN compliant tool can determine the FlowElements which have to be partitioned in this Lane.</td>
</tr>
<tr>
<td>partitionElementRef:</td>
<td>A reference to a BaseElement which specify the partition value and partition type. Using this partition element a BPMN compliant tool can determine the FlowElements which have to be partitioned in this Lane.</td>
</tr>
<tr>
<td>childLaneSet:</td>
<td>A reference to a LaneSet element for embedded Lanes.</td>
</tr>
<tr>
<td>flowElementRefs:</td>
<td>The list of FlowElement partitioned into this Lane according to the partitionElement defined as part of the Lane element</td>
</tr>
</tbody>
</table>

10.8. Process Instances, Unmodeled Activities, and Public Processes

A Process can be executed or performed many times, but each time is expected to follow the steps laid out in the Process model. For example, the Process in Figure 10-1 will occur every Friday, but each instance is expected to perform Task “Receive Issue List,” then Task “Review Issue List,” and so on, as specified in the model. Each instance of a Process is expected to be valid for the model, but some instances might not, for example if the Process has manual Activities, and the performers have not had proper instruction on how to carry out the Process.

In some applications it is useful to allow more Activities and Events to occur when a Process is executed or performed than are contained the Process model. This enables other steps to be taken as needed without changing the Process. For example, instances of the Process in Figure 10-1 might execute or perform an extra Activity between Task “Receive Issue List” and Task “Review Issue List.” These instances are still valid for the Process model in Figure 10-1 because the instances still execute or perform the Activities in the Process, in the order they are modeled and under conditions specified for them.

There are two ways to specify whether unmodeled Activities are allowed to occur in Process instances:

- If the isClosed attribute of a Process has a value of false or no value, then interactions, such as sending and receiving Messages and Events, MAY occur in an instance without additional flow elements in the Process. Unmodeled interactions can still be restricted on particular Sequence Flow in the Process (see next bullet). If the isClosed attribute of a Process has a value of true, then interactions, such as sending and receiving Messages and Events, MAY NOT occur without additional flow elements in the Process. This restriction overrides any unmodeled interactions allowed by Sequence Flow in the next bullet.
If the isImmediate attribute of a Sequence Flow in a Process has a value of false, then other Activities and interactions not modeled in the Process MAY be executed or performed during the Sequence Flow. If the isImmediate attribute has a value of true, then Activities and interactions not modeled in the Process MAY NOT be executed or performed during Sequence Flow. In public Processes (processType attribute has value public) Sequence Flow with no value for isImmediate are treated as if the value were false. In private Processes (processType attribute has value executable or non-executable) Sequence Flow with no value for isImmediate are treated as if the value were true. Executable Processes cannot have a false value for the isImmediate attribute.

Restrictions on unmodeled Activities specified with isClosed and isImmediate apply only under executions or performances (instances) of the Process containing the restriction. These Activities MAY occur in instances of other Processes.

When a Process allows Activities to occur that the Process does not model, those Activities might appear in other Process models. The executions or performances (instances) of these other Processes might be valid for the original Process. For example, a Process might be defined similar to the one in Figure 10-1 that adds an extra Activity between Task “Receive Issue List” and Task “Review Issue List.” The Process in Figure 10-1 might use isClosed or isImmediate to allow other Activities to occur in between Task “Receive Issue List” and Task “Review Issue List.” When the Process is executed or performed, then instances of the other Process (the one with the extra step in between Task “Receive Issue List” and Task “Review Issue List”) will be valid for the Process in Figure 10-1. Modelers can declare that they intend all instances of one Process will be valid for another Process using the supports association between the Processes. During development of these Processes, support might not actually hold, because the association just expresses modeler intent.

A common use for model support is between private and public Processes, see Section “Overview” (page 80). A public Process contain Activities visible to external parties, such as Participants in a Collaboration, while a private Process includes other Activities that are not visible to external parties. The hidden Activities in a private Process are not modeled in the public Process. However, it is expected that instances of the private Process will appear to external parties as if they could be instances of the public Process. This means the private Process supports the public Process (it is expected that all instances of the private Process will be valid for the public one).

A Process that supports another, as a private Process can to a public Process, does not need to be entirely similar to the other Process. It is only required that instances of the Process appear as if they could be instance of the other Process. For example Figure 10-122 shows a public Process at the top with a Send Task and Receive Task. A supporting private Process is shown at the bottom. The private Process sends and receives the same Messages, but using Events instead of Tasks. It also introduces an Activity not modeled in the public Process. However all instances of the private Process will appear as if they could be instances of the public one, because the Messages are sent and received in the order required by the public Process, and the public Process allows unmodeled Activities to occur.
In practice, a public Process looks like an underspecified private Process. Anything not specified in the public Process is determined by the private one. For example, if none of the outgoing Sequence Flow for an Exclusive Gateway have conditions, the private Process will determine which one of the Activities targeted by the Sequence Flow will occur. Another example is a Timer Event with no EventDefinition. The private Process will determine when the timer goes off.
10.9. Auditing

The Auditing element and its model associations allow defining attributes related to auditing. It leverages the BPMN extensibility mechanism. This element is used by FlowElements and Process. The actual definition of auditing attributes is out of scope of this specification. BPMN 2.0 implementations may define their own set of attributes and their intended semantics.

![Auditing Class Diagram]

*Figure 10-123 – Auditing Class Diagram*
10.10. Monitoring

The Monitoring and its model associations allow defining attributes related to monitoring. It leverages the BPMN extensibility mechanism. This element is used by FlowElements and Process. The actual definition of monitoring attributes is out of scope of this specification. BPMN 2.0 implementations may define their own set of attributes and their intended semantics.

11. Conversation

The Conversation diagram is similar to a Collaboration diagram. However, the Pools of a Conversation are not allowed to contain a Process and a Choreography is not allowed to be placed in between the Pools of a Conversation diagram.

The view includes two (2) additional graphical elements that do not exist in other BPMN views:

- A Communication
- A CommunicationLink

A Conversation is set of Message exchanges (Message Flow) that share the same Correlation.

A Conversation is the logical relation of Message exchanges. The logical relation, in practice, often concerns a business object(s) of interest, e.g. “Order,” “Shipment and Delivery,” and “Invoice.” Hence, a Conversation is associated with a set of name-value pairs, or a Correlation Key (e.g. “Order Identifier,” “Delivery Identifier”), which is recorded in Messages that are exchanged. In this way, a Message can be routed to the specific Process instance responsible for receiving and processing the Message.

Figure 11-1 shows a simple example of a Conversation diagram

![Figure 11-1 – A Conversation diagram](image)

Figure 11-2 shows a variation of the example above where the Conversation node has been expanded into its component Message Flow.
Message exchanges are related to each other and reflect distinct business scenarios. The relation is sometimes simple, e.g. a request followed by a response (and can be described as part of a structural interface of a service, e.g. as a WSDL operation definition). However for commercial business transactions managed through Business Processes, the relation can be complex, involving long-running, reciprocal Message exchanges, and that could extend beyond bilateral to complex, multilateral Collaborations. For example, in logistics, stock replenishments involve the following types scenarios: creation of sales orders; assignment of carriers for shipments combining different sales orders; crossing customs/quarantine; processing payment and investigating exceptions.

In addition to an orchestration Process, Conversations are relevant to a Choreography. The difference is that a Choreography provides a multi-party perspective of a Conversation. This is because the Message exchanges modeled using Choreography Activities concern multiple Participants, unlike an orchestration Process where the Message sending and receiving elements relate to one Participant only. Other than the difference in perspective, the notion of Conversation remains the same across Choreography and orchestration - and the Message exchanges of a Conversation will ultimately to be executed through an orchestration Process.

Since Choreography provides a top-down, design-time modeling perspective for Message exchanges and their Conversations, an abstracted view of the all Conversations pertaining to a domain being modeled is available through a Conversation diagram. A Conversation diagram, as depicted in Figure 11-3, shows Conversations (as hexagons) between Participants. This provides a “bird’s eye” perspective of the different Conversations which relate to the domain.
Figure 11-3 – Conversation diagram depicting several conversations between Participants in a related domain

Figure 11-3 above, depicts 13 distinct Conversations between collaborating Participants in a logistics domain. As examples, Retailer and Supplier are involved in a Delivery Negotiations Conversation, and Consignee converses with Retailer and Supplier through Delivery/Dispatch Plan and Shipment Schedule Conversations respectively. More than two participants may be involved in a Conversation, e.g. Consignee, Consolidator and Shipper in Detailed Shipment Schedule. The association of Participants to a Conversation are constrained to indicate whether one or many of Participants are involved. For example, one instance of Retailer converses with one instance of Supplier for Deliver Negotiations. However, one instance of Shipper converses with multiple instances of Carrier (indicated by the multiplicity symbol “*” near Carrier) for Carrier Planning. Note, multiplicity in constraints of Conversation diagrams means one or more (not zero or more).

The behavior of different Conversations is modeled through separate Choreographies, detailing the Message exchange sequences. In practice, Conversations which are closely related could be combined in the same Choreography models – e.g. a Message exchange in the Delivery Negotiation leads to Shipment Schedule, Delivery Planning and Delivery/Dispatch Conversations and these could be combined together in the same Choreography. Alternatively, they could be separated in different models.

Proposal for:
Business Process Model and Notation (BPMN), v2.0

330
Figure 11-4 shows how Message exchanges can be expanded from a Conversation in the Conversation diagram of Figure 11-3, above. This expands the Conversation with the Message Flow, providing a structural view of a Conversation without the “clutter” of sequencing details in the same diagram. Figure 11-4 also indicates the Correlation Key involved in the Message Flow of the Conversation. For example, Order Id is required for in all Messages of Message Flow in Delivery Negotiation. In addition, some Message Flow also require Variation Id (for dealing with shipment variations on a per line item basis).

---

**Figure 11-4 – Conversational view choreographies**

In Figure 11-3, above, a hierarchical structure of Conversations can be seen with one set of Message Flow occurring within another in a parent-child relationship. In particular, after Planned Order Variations (keyed on Order Id) at the parent, a number of Message Flow of the child follow till Retailer Order and Delivery Variations Ack (keyed on Variable Id and Order Id). The remaining Message Flow (keyed on Order Id) are at the parent level. The child Conversation, as such, is part of the parent Conversation. Nesting is indicated graphically on a Conversation symbol (by a “+”) to alert the modeler that one of more Conversations can take place inside the Conversation exposed in the Conversation diagram. Nesting can go to an arbitrary number of levels.

A common dependency between Conversations is overlap. Overlap occurs when two or more Conversations have some Message exchanges in common but not others. As an example in Figure 11-3, above, a Message is sent as part of Detailed Shipment Schedule (keyed on Carrier Schedule Id) to trigger
Delivery Monitoring (keyed on Shipment Id). During Delivery Monitoring, Message could be sent to Detailed Shipment Schedule (to request modifications when transportation exceptions occur).

Splits and joins are special types of overlap scenarios. A Conversation split arises when, as part of a Conversation, a message is exchanged between two or more Participants that at the same time spawns a new, distinct Conversation (either between the same set of Participants or another set). Additionally, no further Message exchanges are shared by the split Conversations as well as no subsequent merges of them occur. An example is Delivery Planning which leads to Carrier Planning and Special Cover. A Conversation join occurs when several Conversations are merged into one Conversation and no further Message exchanges occur in the original Conversations, i.e. these Conversations are finalized. The generalization of a split and join is a Conversation refactor where Conversations are split into parallel Conversations and then are merged at a later point in time.

Figure 11-5 displays the Conversation class diagram. When a Conversation is defined it is contained within Definitions.
Figure 11-5 – The Conversation Metamodel
The Conversation element inherits the attributes and model associations of CallableElement (see Table 8-30), InteractionSpecification (see Table 8-48), and ConversationContainer (see Table 11-2). Table 11-1 presents the additional model associations for the Conversation element:

Table 11-1 – Conversation Model Associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>

<td>This association specifies correlationKeys used to associate Messages to a particular Conversation.</td>
</tr>
<tr>
<td>CorrelationKey [0..*]</td>
<td></td>
</tr>
<tr>
<td>messageFlowRefs:</td>
<td>A reference to all Message Flow (and consequently Messages) included in the Collaboration or Choreography where the Conversation is contained. This is only used when the Conversation is contained in a Choreography or Collaboration, not when the Conversation is reusable (and contained in Definitions).</td>
</tr>
<tr>
<td>MessageFlow [0..*]</td>
<td></td>
</tr>
</tbody>
</table>

Note: The CallableElement attributes supportedInterfaceRefs, ioSpecification, and ioBinding are not applicable to a Conversation.

11.1. Conversation Container

ConversationContainer is an abstract super class for the Conversation diagrams and defines the superset of elements that are contained in those diagrams. Basically, a ConversationContainer contains ConversationNodes, which are Communication (see page 336), Sub-Conversation (see page 336), and Call Conversation (see page 337).

There are two (2) types of FlowElementContainers (see Figure 11-6): Conversation and Sub-Conversation.
Figure 11-6 – A ConversationContainer element

The ConversationContainer element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 11-2 presents the additional model associations for the ConversationContainer element:

Table 11-2 – ConversationContainer Model Associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>conversationNodes: ConversationNode [0..*]</td>
<td>This association specifies the particular ConversationNodes contained in a ConversationContainer. ConversationNodes are Communications, Sub-Conversations, and Call Conversations.</td>
</tr>
<tr>
<td>artifacts: Artifact [0..*]</td>
<td>This attribute provides the list of Artifacts that are contained within the ConversationContainer.</td>
</tr>
</tbody>
</table>

11.2. Conversation Node

ConversationNode is the abstract super class for all elements that can appear in a Conversation diagram, which are Communication (see page 336), Sub-Conversation (see page 336), and Call Conversation (see page 337).

ConversationNodes are linked to and from Participants using Communication Links (see page 338).
The ConversationNode element inherits the attributes and model associations of BaseElement (see Table 8-5). Table 11-3 presents the additional attributes and model associations for the ConversationNode element:

**Table 11-3 – ConversationNode Model Associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>Name is a text description of the ConversationNode.</td>
</tr>
<tr>
<td>participantRefs: Participant [0..*]</td>
<td>This provides the list of Participants that are used in the ConversationNode from the list provided by the ConversationNode’s parent Conversation.</td>
</tr>
</tbody>
</table>

### 11.3. Communication

A Communication is an atomic element for a Conversation diagram. It represents a set of Message Flow grouped together based on a single CorrelationKey. A Communication will involve two (2) or more Participants.

- A Communication is a hexagon that MUST be drawn with a single thin line (see Figure 11-7).

![Figure 11-7 – A Communication element](image)

The Communication element inherits the attributes and model associations of ConversationNode (see Table 11-3) and presents the additional model associations for the Communication element:

**Table 11-4 – Communication Model Associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>correlationKeyRef: CorrelationKey [0..1]</td>
<td>This is a reference to one of the Conversation’s correlationKeys, which is used to group Message Flow for the Communication.</td>
</tr>
<tr>
<td>messageFlowRefs: MessageFlow [0..*]</td>
<td>A reference to all Message Flow (and consequently Messages) included in a Communication.</td>
</tr>
</tbody>
</table>

### 11.4. Sub-Conversation

A Sub-Conversation is a ConversationNode that is a hierarchical division within the parent Conversation. A Sub-Conversation is a graphical object within a Conversation, but it also can be “opened up” to show the lower-level Conversation, which consist of Message Flow, Communications, and/or other Sub-Conversations. The Sub-Conversation shares the Participants of its parent Conversation.

Proposal for:
Business Process Model and Notation (BPMN), v2.0
- A Sub-Conversation is a hexagon that MUST be drawn with a single thin line (see Figure 11-8).
- The Sub-Conversation marker MUST be a small square with a plus sign (+) inside. The square MUST be positioned at the bottom center of the shape.

![Sub-Conversation marker](image)

**Figure 11-8 – A compound Conversation element**

The Sub-Conversation element inherits the attributes and model associations of ConversationNode (see Table 11-3). Table 11-5 presents the additional model associations for the Sub-Conversation element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>correlationKeyRefs:</td>
<td>This is a reference to the Conversation’s correlationKeys, which are</td>
</tr>
<tr>
<td>CorrelationKeys [0..*]</td>
<td>used to group Message Flow for the Sub-Conversation.</td>
</tr>
</tbody>
</table>

**Table 11-5 – Sub-Conversation Model Associations**

11.5. Call Conversation

A Call Conversation identifies a place in the Conversation where a global Conversation or a GlobalCommunication is used.

- If the Call Conversation calls a GlobalCommunication, then the shape will be the same as a Communication, but the boundary of the shape will MUST have a thick line (see Figure 11-9).
- If the Call Activity calls a Conversation, then the shape will be the same as a Sub-Conversation, but the boundary of the shape will MUST have a thick line (see Figure 11-10).

![Call Conversation shape](image)

**Figure 11-9 – A Call Conversation calling a GlobalCommunication**

![Call Conversation shape with marker](image)

**Figure 11-10 – A Call Conversation calling a Conversation**
The Call Conversation element inherits the attributes and model associations of ConversationNode (see Table 11-3). Table 11-6 presents the additional model associations for the Communication element:

**Table 11-6 – Communication Model Associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>calledElementRef:</td>
<td>The element to be called, which will be either a Conversation or a GlobalCommunication. Other CallableElements, such as Process, GlobalTask, Choreography, and GlobalChoreographyTask MUST NOT be called by the Call Conversation element.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>participantAssociations:</td>
<td>This attribute provides a list of mappings from the Participants of a referenced GlobalCommunication or Conversation to the Participants of the parent Conversation.</td>
</tr>
</tbody>
</table>

11.6. Global Communication

A GlobalCommunication is a reusable, atomic Communication definition that can be called from within any Conversation by a Call Conversation.

The GlobalCommunication element inherits the attributes and model associations of InteractionSpecification (see Table 8-48) and CallableElement (see Table 8-30). Table 11-7 presents the additional model associations for the GlobalCommunication element:

**Table 11-7 – GlobalCommunication Model Associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>correlationKeys:</td>
<td>This association specifies correlationKeys used to associate Message Flow to the GlobalCommunication.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: The CallableElement attributes supportedInterfaceRefs, ioSpecification, and ioBinding are not applicable to a Global Communication.

11.7. Communication Link

Conversation Links are used to connect ConversationNodes to and from Participants (Pools). If the target Participant has a participantMultiplicity of greater than one (1), then the end of the connector is forked (see Figure 11-11).
A Conversation Link; the connection between a Participant and a Conversation Node

The Conversation Link source is forked if there are multiple connections

Figure 11-11 – A Conversation Link element

There is not a specific BPMN metamodel element to represent the Conversation Link. Instead, the graphical element is derived from the relationship between ConversationNode and Participant (as seen in Figure 11-12).

11.8. Conversation Package XML Schemas

Table 11-8 – Call Conversation XML schema

12. Choreography

Note: The content of this chapter is required for BPMN Choreography Modeling Conformance or for BPMN Complete Conformance. However, this chapter is not required for BPMN Process Modeling Conformance, BPMN Process Execution Conformance, or BPMN BPEL Process Execution Conformance. For more information about BPMN conformance types, see page 28.

A Choreography is a type of process, but differs in purpose and behavior from a standard BPMN Process. A standard Process, or an Orchestration Process (see page 53) is more familiar to most process modelers and defines the flow of Activities of a specific PartnerEntity or organization. In contrast, Choreography formalizes the way business Participants coordinate their interactions. The focus is not on orchestrations of the work performed within these Participants, but rather on the exchange of information (Messages) between these Participants.

Another way to look at Choreography is to view it as a type of business contract between two (2) or more organizations.

This entails Message (document) exchanges in an orderly fashion: e.g. first a retailer sends a purchase order request to a supplier; next the supplier either confirms or rejects intention to investigate the order; then supplier proceeds to investigate stock for line-items and seeks outside suppliers if necessary; accordingly the supplier sends a confirmation or rejection back; during this period the retailer can send requests to vary the order, etc.

Message exchanges between partners go beyond simple request-response interactions into multi-cast, contingent requests, competing receives, streaming and other service interaction patterns (REF for SIP). Moreover, they cluster around distinct scenarios such as: creation of sales orders; assignment of carriers of shipments involving different sales orders; managing the “red tape” of crossing customs and quarantine; processing payment and investigating exceptions. A Choreography is a definition of expected behavior, basically a procedural business contract, between interacting Participants (see page 24 for more information on Participants). It brings Message exchanges and their logical relation as Conversations into view. This allows partners to plan their Business Processes for inter-operation without introducing conflicts. An example of a conflict could arise if a retailer was allowed to send a variation on a purchase order immediately after sending the initial request. The Message exchange sequences in Choreography models need to be reflected in the orchestration Processes of participants. A Choreography model makes it possible to derive the Process interfaces of each partner’s Process (REF: Decker & Weske, 2007).

To leverage the familiarity of flow charting types of Process models, BPMN Choreographies also have “activities” that are ordered by Sequence Flow. These “activities” consist of one (1) or more interactions between Participants. These interactions are often described as being message exchange patterns (MEPs). A MEP is the atomic unit (“Activity”) of a Choreography.

Some MEPs involve a single Message (e.g., a “Customer” requests an “Order” from a “Supplier”). Other MEPs will involve two (2) Messages in a request and response format (e.g., a “Supplier” request a “Credit Rating” from a “Financial Institution,” who then returns the “Credit Rating” to the “Supplier”). There can be even more complex MEPs that involve error Messages, for example.

A single MEP is defined as a BPMN Choreography Task (see page 350). Thus, a Choreography defines the order in which Choreography Tasks occur. Choreography Sub-Processes allow the composition/decomposition of Choreographies.
Choreographies are designed in BPMN to allow stand-alone, scalable models of these Participant interactions. However, since BPMN provides other Business Process modeling views, Choreographies are designed to fit within BPMN Collaboration diagrams to display the relationship between the Choreography and Orchestration Processes (thus, expanding BPMN 1.2 capabilities—see page 143, above, for more information on Collaborations, and page 394 for Choreographies within Collaborations).

Figure 12-1 shows displays the metamodel of the key BPMN elements that contribute to Choreography modeling. The sections of this chapter will describe the characteristics of these elements and how they are used in a Choreography.

Figure 12-1 – The Choreography metamodel

The Choreography element inherits the attributes and model associations of CallableElement (see Table 8-30) and of FlowElementContainer (see Table 8-46). Table 12-1 presents the additional model associations of the Choreography element.
Table 12-1 – Choreography Model Associations

12.1. Basic Choreography Concepts

A key to understanding Choreographies and how they are used in BPMN is their relationship to Pools (see page 124 for more information on Pools). Choreographies exist outside of or in between Pools. A Process, within a Pool, represents the work of a specific PartnerEntity (e.g., “FedEx”), often substituted by a PartnerRole (e.g., “Shipper”) when a PartnerEntity is not identified and can be decided later. The PartnerEntity/PartnerRole is called a Participant in BPMN. Pools are the graphical representation of Participants. A Choreography, on the other hand, is a different kind of process. A Choreography defines the sequence of interactions between Participants. Thus, a Choreography does not exist in a single Pool—it is not the purview of a single Participant. Each step in the Choreography involves two (2) or more Participants.
Participants (these steps are called Choreography Activities—see below). This means that the Choreography, in BPMN terms, is defined outside of any particular Pool.

The key question that needs to be continually asked during the development of a Choreography is “what information do the Participants in the Choreography have?” Basically, each Participant can only understand the status of the Choreography through observable behavior of the other Participants—which are the Messages that have been sent and received. If there are only two (2) Participants in the Choreography, then it is very simple—both Participants will be aware of who is responsible for sending the next Message. However, if there are more than two (2) Participants, then the modeler must be careful to sequence the Choreography Activities in such a way that the Participants know when they are responsible for initiating the interactions.

Figure 12-2 presents a sample Choreography. The details of Choreography behavior and elements will be described in the sections below.

Figure 12-2 – An example of a Choreography

To illustrate the correspondence between Collaboration and Choreography, consider an example from logistics. Figure 12-3 shows a Collaboration where the Pools are expanded to reveal orchestration details per participant (for Shipper, Retailer etc). Message Flow connect the elements in the different Pools related to different participants, indicating Message exchanges. For example, a Planned Order Variations Message is sent by the Supplier to the Retailer; the corresponding send and receive have been modeled using regular BPMN messaging Events. Also, a number of Messages of the same type being sent, for example a number of Retailer Order and Delivery Variations Messages can be sent from the Retailer to the Supplier, indicated by respective multi-instances constructs (for brevity, the actual elements for sending/receiving inside the multi-instances construct have been omitted).
The scenario modeled in Figure 12-4 entails shipment planning for the next supply replenishment variations: the Supplier confirms all previously accepted variations for delivery with the Retailer; the Retailer sends back a number of further possible variations; the Supplier requests to the Shipper and Consignee possible changes in delivery; accordingly, the Retailer interacts with the Supplier and Consignee for final confirmations.

A problem with model interconnections for complex Choreographies is that they are vulnerable to errors – interconnections may not be sequenced correctly, since the logic of Message exchanges is considered from each partner at a time. This in turn leads to deadlocks. For example, consider the PartnerRole of Retailer in Figure 12-4 and assume that, by error, the order of Confirmation Delivery Schedule and Retailer Confirmation received (far right) were swapped. This would result in a deadlock since both, Retailer and Consignee would wait for the other to send a Message. Deadlocks in general, however, are not that obvious and might be difficult to recognize in a Collaboration.

Figure 12-4 shows the Choreography corresponding to the Collaboration of Figure 12-3 above.
12.2. Data

A Choreography does not have a central control mechanism and, thus, there is no mechanism for maintaining any central Process (Choreography) data. Thus, any element in a Process that would normally depend on conditional or assignment expressions, would not have any central source for this data to be maintained and understood by all the Participants involved in the Choreography.

As mentioned above, neither Data Objects nor Repositories are used in Choreographies. Both of these elements are used exclusively in Processes and require the concept of a central locus of control. Data Objects are basically variables and there would be no central system to manage them. Data can be used in expressions that are used in Exclusive Gateways, but only that data which has been sent through a Message in the Choreography.

12.3. Use of BPMN Common Elements

Some BPMN elements are common to both Process and Choreography diagrams, as well as Collaboration; they are used in these diagrams. The next few sections will describe the use of Messages, Message Flow, Participants, Sequence Flow, Artifacts, Correlations, Expressions, and Services in Choreography.

The key graphical elements of Gateways and Events are also common to both Choreography and Process. Since their usage has a large impact, they are described in major sections of this chapter (see page 369 for Events and page 375 for Gateways).
12.3.1. Sequence Flow

Sequence Flow are used within Choreographies to show the sequence of the Choreography Activities, which may have intervening Gateways. They are used in the same way as they are in Processes. They are only allowed to connect with other Flow Objects. For Processes, they can only connect Events, Gateways, and Activities. For Choreographies, they can only connect Events, Gateways, and Choreography Activities (see Figure 12-5).

**Figure 12-5 – The use of Sequence Flow in a Choreography**

There are two additional variations of Sequence Flow:

- **Conditional Sequence Flow**: Conditions can be added to Sequence Flow in two situations:
  - From Gateways: Outgoing Sequence Flow have conditions for Exclusive and Inclusive Gateways. The data referenced in the conditions must be visible to two (2) or more Participants in the Choreography. The data becomes visible if it is part of a Message that had been sent (previously) within the Choreography. See pages 375 and 383 for more information about how Exclusive and Inclusive Gateways are used in Choreography.
  - From Choreography Activities: Outgoing Sequence Flow may have conditions for Choreography Activities. Since these act similar to Inclusive Gateways, the Conditional Sequence Flow can be used in Choreographies. The conditions have the same restrictions that apply to the visibility of the data for Gateways.

- **Default Sequence Flow**: For Exclusive Gateways, Inclusive Gateways, and Choreography Activities that have Conditional Sequence Flow, one of the outgoing Sequence Flow may be a Default Sequence Flow. Because the other outgoing Sequence Flow will have appropriately visible of data as described above, the Participants would know if all the other conditions would be false, thus the Default Sequence Flow would be selected and the Choreography would move down that Sequence Flow.

In some applications it is useful to allow more Messages to be sent between Participants when a Choreography is carried out than are contained the Choreography model. This enables Participants to exchange other Messages as needed without changing the Choreography. There are two ways to specify this:
• If the isClosed attribute of a Choreography has a value of false or no value, then Participants MAY send Messages to each other without additional Choreography Activities in the Choreography. Unmodeled messaging can be restricted on particular Sequence Flow in the Choreography, see next bullet. If the isClosed attribute of a Choreography has a value of true, then Participants MAY NOT send Messages to each other without additional Choreography Activities in the Choreography. This restriction overrides any unmodeled messaging allowed by Sequence Flow in the next bullet.

• If the isImmediate attribute of a Sequence Flow has a value of false or no value, then Participants MAY send Messages to each other between the elements connected by the Sequence Flow without additional Choreography Activities in the Choreography. If the isImmediate attribute of a Sequence Flow has a value of true, then Participants MAY NOT send Messages to each other between the elements connected by the Sequence Flow without additional Choreography Activities in the Choreography. The value of isImmediate attribute of a Sequence Flow has no effect if the isClosed attribute of the containing Choreography has a value of true.

Restrictions on unmodeled messaging specified with isClosed and isImmediate applies only under the Choreography containing the restriction. PartnerEntities and PartnerRoles of the Participants MAY send Messages to each other under other Choreographies, Collaborations, and Conversations.

12.3.2. Artifacts

Both Text Annotations and Groups can be used within Choreographies and all BPMN diagrams. There are no restrictions on their use.

12.3.3. Correlations

Correlation will only indirectly impact a Choreography.

12.4. Choreography Activities

A Choreography Activity represents a point in a Choreography flow where an interaction occurs between two (2) or more Participants.

The Choreography Activity class is an abstract element, sub-classing from FlowElement (as shown in Figure 12-6). When Choreography Activities are defined they are contained within a Choreography or a Choreography Sub-Process, which are FlowElementContainers (other FlowElementContainers are not allowed to contain Choreography Activities).
The Choreography Activity element inherits the attributes and model associations of FlowElement (see Table 8-45) through its relationship to FlowNode. Table 12-2 presents the additional model associations of the Choreography Activity element.

### Table 12-2 – Choreography Activity Model Associations

<table>
<thead>

</tr>
<tr>
<td>initiatingParticipant:</td>
<td>One (1) of the Participants will be the one that initiates the Choreography Activity.</td>
</tr>
</tbody>
</table>

### 12.4.1. Choreography Task

A Choreography Task is an atomic Activity in a Choreography Process. It represents an Interaction, which is a coherent set (1 or more) of Message exchanges between two (2) Participants. Using a Collaboration diagram to view these elements (see page 143 for more information on Collaboration), we
would see the two (2) Pools representing the two (2) Participants of the Interaction (see Figure 12-7). The communication between the Participants is shown as a Message Flow.

![Figure 12-7 – A Collaboration view of Choreography Task elements](image)

In a Choreography diagram, this Interaction is collapsed into a single object, a Choreography Task. The name of the Choreography Task and each of the Participants are all displayed in the different bands that make up the shape’s graphical notation. There are two (2) more Participant Bands and one Task Name Band (see Figure 12-8).

![Figure 12-8 – A Choreography Task](image)
The interaction defined by a **Choreography Task** can be shown in an expanded format through a **Collaboration** diagram (see Figure 12-7—see page 43 for more information on **Collaborations**). In the **Collaboration** view, the **Participants** of the Choreography Task Participant Band’s will be represented by **Pools**. The interaction between them will be a **Message Flow**.

**Figure 12-9 – A Choreography Task**

**Figure 12-10 – A two-way Choreography Task**
In a Choreography Diagram, the Choreography Task object shares the same shape as a Task or any other BPMN Activity, which is a rectangle that has rounded corners.

- A Choreography Task is a rounded corner rectangle that MUST be drawn with a single line.
- The use of text, color, size, and lines for a Choreography Task MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.

The three (3) bands in the Choreography Task shape provide the distinction between this type of Task and an Orchestration Task (in a traditional BPMN diagram).

As with a standard Orchestration Task, the Choreography Task may have internal markers to show how the Choreography Task may be repeated. There are two types of internal markers (see Figure 12-12).

- A Choreography Task MAY have only one of the two (2) markers at one time.
- The marker for a Choreography Task that is a standard loop MUST be a small line with an arrowhead that curls back upon itself.
- The marker for a Choreography Task that is multi-instance MUST be a set of three vertical lines.
- The marker that is present MUST be centered at the bottom of the Task Name Band of the shape.
Figure 12-12 – Choreography Task Markers

Figure 12-13 – The Collaboration view of a looping Choreography Task
Participant A

Send Message

Participant B

Receive Message

There are situations when a Participant for a Choreography Task is actually a multi-instance Participant. A multi-instance Participant represents a situation where there are more than one possible related Participants (PartnerRoles/PartnerEntities) that may be involved in the Choreography. For example, in a Choreography that involves the shipping of a product, there may be more than one type of shipper used, depending on the destination. When a Participant in a Choreography contains multiple instances, then a multi-instance marker will be added to the Participant Band for that Participant (see Figure 12-15).

- The marker for a Choreography Task that is multi-instance MUST be a set of three vertical lines.
- The marker that is present MUST be centered at the bottom of the Participant Band of the shape.
- The width of the Participant Band will be expanded to contain both the name of the Participant and the multi-instance marker.

Figure 12-15 – A Choreography Task with a multiple Participant
The Choreography Task element inherits the attributes and model associations of Choreography Activity (see Table 12-2). Table 12-3 presents the additional model associations of the Choreography Task element.

**Table 12-3 – Choreography Task Model Associations**

<table>

<td>Although not graphical represented, Choreography Task contain one (1) or more Message Flow that represent the interaction(s) between the Participants referenced by the Choreography Task.</td>
</tr>
</tbody>
</table>

### 12.4.2. Choreography Sub-Process

A Choreography Sub-Process is a compound Activity in that it has detail that is defined as a flow of other Activities, in this case, a Choreography. Each Choreography Sub-Process involves two (2) or more Participants. The name of the Choreography Sub-Process and each of the Participants are all displayed in the different bands that make up the shape’s graphical notation. There are two (2) more Participant Bands and one Sub-Process Name Band.

The Choreography Sub-Process can be in a collapsed view that hides its details (see Figure 12-17) or a Choreography Sub-Process can be expanded to show its details (a Choreography Process) within the Choreography Process in which it is contained (see Figure 12-19). In the collapsed form, the Sub-Process object uses a marker to distinguish it as a Choreography Sub-Process, rather than a Choreography Task.
- The **Sub-Process** marker MUST be a small square with a plus sign (+) inside. The square MUST be positioned at the bottom center of the **Sub-Process Name Band** within the shape.

![Diagram](image)

**Figure 12-17 – A Choreography Sub-Process**

**Figure 12-18** shows an example of a potential **Collaboration** view of the above **Choreography Sub-Process**.

![Diagram](image)

**Figure 12-18 – A Collaboration view of a Choreography Sub-Process**

**Figure 12-19** shows an example of an **expanded** **Choreography Sub-Process**.
Figure 12-19 – An expanded Choreography Sub-Process

Figure 12-20 shows an example of a potential Collaboration view of the above Choreography Sub-Process.
The **Parent Choreography Sub-Process** (Expanded)

The Choreography Activity shares the same shape as a Sub-Process or any other BPMN Activity, which is in this state.

- A Choreography Sub-Process is a rounded corner rectangle that MUST be drawn with a single thin line.
- The use of text, color, size, and lines for a Choreography Sub-Process MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 63.

The three (3) or more partitions in the Choreography Sub-Process shape provide the distinction between this type of Task and an Orchestration Sub-Process (in a traditional BPMN diagram).

It is possible for a Choreography Sub-Process to involve more than two (2) Participants. In this case, an additional Participant Band will be added to the shape for each additional Participant (see Figure 12-21). The ordering and position of the Participant Band (either in the upper or lower positions) is up to the modeler or modeling tool. In addition, any Participant Band beyond the first two optional; it is displayed at the discretion of the modeler or modeling tool. However, each Participant Band that is added MUST be added to the upper and lower sections of the Choreography Sub-Process in an alternative manner.
As with a standard Orchestration Sub-Process, the Choreography Sub-Process may have internal markers to show how the Choreography Sub-Process may be repeated. There are two types of internal markers (see Figure 12-22):

- A Choreography Sub-Process MAY have only one of the two (2) markers at one time.
  - The marker for a Choreography Sub-Process that is a standard loop MUST be a small line with an arrowhead that curls back upon itself.
  - The marker for a Choreography Sub-Process that is multi-instance MUST be a set of three vertical lines.
  - The marker that is present MUST be centered at the bottom of the Sub-Process Name Band of the shape.

There are situations when a Participant for a Choreography Sub-Process is actually a multi-instance Participant. A multi-instance Participant represents a situation where there are more than one possible related Participants (PartnerRoles/PartnerEntities) that may be involved in the Choreography. For example, in a Choreography that involves the shipping of a product, there may be more than one type of shipper used, depending on the destination. When a Participant in a Choreography contains multiple instances, then a multi-instance marker will be added to the Participant Band for that Participant (see Figure 12-23):

- The marker for a Choreography Sub-Process that is multi-instance MUST be a set of three vertical lines.
- The marker that is present MUST be centered at the bottom of the Participant Band of the shape.
- The width of the Participant Band will be expanded to contain both the name of the Participant and the multi-instance marker.
This includes Compensation Event Sub-Processes (contained within a Choreography Sub-Process) as well as the external Compensation Activity connected through an Association.

The Choreography Sub-Process element inherits the attributes and model associations of Choreography Activity (see Table 12-2). The Choreography Sub-Process does not have any additional attributes or model associations.

12.4.3. Call Choreography Activity

A Call Choreography Activity identifies a point in the Process where a global Choreography or a Global Choreography Task is used. The Call Choreography Activity acts as a place holder for the inclusion of the Choreography element it is calling. This pre-defined called Choreography element becomes a part of the definition of the parent Choreography.

A Call Choreography Activity object shares the same shape as the Choreography Task and Choreography Sub-Process, which is a rectangle that has rounded corners, two (2) or more Participant Bands, and an Activity Name Band. However, the target of what the Choreography Activity calls will determine the details of its shape.

- If the Call Choreography Activity calls a Global Choreography Task, then the shape will be the same as a Choreography Task, but the boundary of the shape will MUST have a thick line (see Figure 12-24).
- If the Call Choreography Activity calls a Choreography, then there are two (2) options:
  - The details of the called Choreography can be hidden and the shape will be the same as a collapsed Choreography Sub-Process, but the boundary of the shape MUST have a thick line (see Figure 12-25).
  - The details of the called Choreography can be shown and the shape will be the same as an expanded Choreography Sub-Process, but the boundary of the shape MUST have a thick line (see Figure 12-26).
Figure 12-24 – A Call Choreography Activity calling a Global Choreography Task

</tr>
</tbody>
</table>

12.4.4. Global Choreography Task

A GlobalChoreographyTask is a reusable, atomic Choreography Task definition that can be called from within any Choreography by a Call Choreography Activity.
The GlobalChoreographyTask element inherits the attributes and model associations of CallableElement (see Table 8-30) and InteractionSpecification (see Table 8-48). Table 12-5 presents the additional model associations of the GlobalChoreographyTask element.

</tbody>
</table>

### 12.4.5. Looping Activities

Both Choreography Sub-Processes can have standard loops and multi-instances. The data used to define the loop conditions must be visible to all Participants.

### 12.4.6. The Sequencing of Activities

There are constraints on how Choreography Activities can be sequenced (through Sequence Flow) in a Choreography. These constraints are due to the limited visibility of the Participants, which only know of the progress of the Choreography by the Messages that occur. When a Participant sends or receives a Message, then that Participant knows exactly how far the Choreography has progressed. This means that the ordering of Choreography Activities must take into account when the Participants send or receive Messages so that they Participants are not required to guess about when it is their turn to send a Message.

The basic rule of Choreography Activity sequencing is this:

- The Initiator of a Choreography Activity MUST have been involved (as Initiator or Receiver) in the previous Choreography Activity.

Of course, the first Choreography Activity in a Choreography does not have this constraint.

Figure 12-28 shows a sequence of two (2) Choreography Activities that follow this constraint. “Participant B” is the Initiator of “Choreography Task 2” after being the Receiver in “Choreography Task 1.” While there is no requirement that “Participant B” sends the Message immediately, since there may be internal work that the Participant needs to do prior to the Message. But in this situation there is no ambiguity that “Participant B” will be the Initiator of the next Choreography Task. “Participant C” does not know exactly when the Message will arrive from “Participant B,” but “Participant C” knows that one will arrive and there are not any additional requirements on the Participant until the Message arrives.
The Initiator of a Choreography Task must be involved in the previous Activity.

**Figure 12-28 – A valid sequence of Choreography Activities**

Naturally, the sequence of Choreography Activities shown in Figure 12-28, above can be expanded into a Collaboration diagram to show how the sequence can be enforced. Figure 12-29 shows the corresponding Collaboration. The diagram shows how the Activities within the individual Pools fit with the design of the Choreography.
When determining a valid sequence of **Choreography Tasks**, it is important to consider the type of **Choreography Tasks** that are being used. A single **Choreography Task** can be used for one (1) or more **Messages**. Most of the time there will be one (1) or two (2) **Messages** for a **Choreography Task**. Figure 12-30 shows a sequence of **Choreography Tasks**, the first one being a two-way interaction, where the initiator sends a **Message** and gets a response from the other **Participant**.

**Figure 12-29 – The corresponding Collaboration for a valid Choreography sequence**

**Figure 12-30 – A valid sequence of Choreography Activities with a two-way Activity**
Figure 12-31 shows the corresponding Collaboration and how the two Choreography Tasks are reflected in the Processes within the Pools. The Choreography Task that has two Messages will be reflected by three Process Tasks. Usually in these cases, the initiating Participant will use a single Activity to handle both the sending and receiving of the Messages. A BPMN Service Task can be used for this purpose and these types of Tasks are often referred to as “request-response” Tasks for Choreography modelers.

![Diagram of Figure 12-31](image)

**Participant A**
- Send and Receive Messages
- Send Message
- M1
- M3

**Participant B**
- Receive Message
- Send Message
- M2

**Participant C**
- Receive Message

Figure 12-31 – The corresponding Collaboration for a valid Choreography sequence with a two-way Activity

Figure 12-32 shows how a sequence of Choreography Activities can be designed that would be invalid in the sense that an Initiating Participant would not know when the appropriate time would be to send a Message. In this example, “Participant A” is scheduled to send a Message to “Participant C” after “Participant B” sends a Message to “Participant C.” However, “Participant A” will not know when the Message from “Participant B” has been sent. So, there is no way to enforce the sequence that is modeled in the Choreography.
Not Valid — This Participant would not know when to send the Message

**Figure 12-32 — An invalid sequence of Choreography Activities**

*Figure 12-33* shows the Collaboration view of the above Choreography diagram. It becomes clear that “Participant A” will not know the appropriate time to send Message “M3” to “Participant C.” If the Message is sent too soon, then “Participant C” will not be prepared to receive it. Thus, as a Choreography, the model in Figure 12-32, above, cannot be enforced.

369 Business Process Model and Notation (BPMN), v2.0

12.5. Events

12.5.1. Start Events

Start Events provide the graphical marker for the start of a Choreography. They are used much in the same way as they are used for a Process (see “Start Event” on page 244).

---

Figure 12-33 – The corresponding Collaboration for an invalid Choreography sequence

Not Valid –
There is no way to enforce the sequence of “M2” and “M3”
This table shows how the types of Start Events are applied to Choreography.

### Table 12-6 – Use of Start Events in Choreography

<table>
<thead>
<tr>
<th>Type of Event</th>
<th>Usage in Choreography?</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>None</strong></td>
<td>Yes. This is really just a graphical marker since the arrival of the first Message in the Choreography is really the Trigger for the Choreography. Sub-Processes, however, we should look at. The Parent Process may be considered the Trigger. Not used in an Event Sub-Process.</td>
</tr>
<tr>
<td><strong>Message</strong></td>
<td>No. A Message Start Event, in a stand-alone Choreography, has no way to show who the senders or receivers of the Message should be. A Choreography Task should be used instead. Thus, a None Start Event should be used as a graphical marker for the “start” of the Choreography. Not used in an Event Sub-Process.</td>
</tr>
<tr>
<td><strong>Timer</strong></td>
<td>Yes. All Participants have to have an agreement to the approximate time. Can be used in an Event Sub-Process.</td>
</tr>
<tr>
<td><strong>Escalation</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Error</strong></td>
<td>No. An Error is only visible to a single Participant. That Participant will have to send a Message to the other Participants.</td>
</tr>
<tr>
<td><strong>Compensation</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Conditional</strong></td>
<td>[Used only for Event Sub-Processes] Yes. This is actually determined internal to Participant, but then the other Participants know this has happened based the first interaction that follows.</td>
</tr>
<tr>
<td><strong>Signal</strong></td>
<td>Yes. The source of the Signal is not required (and may not even be a Participant in the Choreography). There are no specific recipients of a Signal. All Participants of the Choreography (to comply) must be able to see the Signal. Can be used in an Event Sub-Process.</td>
</tr>
<tr>
<td><strong>Multiple</strong></td>
<td>Yes. But they can only be Multiple Signals or Timers. As in Orchestration, this acts like an OR. Any one of the incoming Signals will Trigger the Choreography. Any Signal that follows would create a separate instance of the Choreography. Can be used in an Event Sub-Process.</td>
</tr>
</tbody>
</table>
### 12.5.2. Intermediate Events

#### Table 12-7 – Use of Intermediate Events in Choreography

<table>
<thead>
<tr>
<th>Type of Event</th>
<th>Usage in Choreography?</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>None</strong>: in Normal Flow</td>
<td>Yes. However, this really doesn’t have much meaning other than just documenting that a specific point has been reached in the Choreography. There would be no Message exchange or any delay in the Choreography.</td>
</tr>
<tr>
<td><strong>None</strong>: Attached to Activity boundary</td>
<td>No. There would be no way for Participants to know when the Activity should be interrupted.</td>
</tr>
<tr>
<td><strong>Message</strong>: in Normal Flow</td>
<td>No. A Message Intermediate Event, in a stand-alone Choreography, has no way to show who the senders or receivers of the Message should be. A Choreography Task should be used instead. Also, would the Event be a Catch or a Throw?</td>
</tr>
<tr>
<td><strong>Message</strong>: Attached to Activity boundary</td>
<td>Yes. Only for Choreography Tasks. The Intermediate Event has to be attached to the Participant Band of the receiver of the Message (since it is a catch Event). The sender of the message has to be the other Participant of the Choreography Task.</td>
</tr>
<tr>
<td><strong>Message</strong>: Use in Event Gateway</td>
<td>No. A Message Intermediate Event, in a stand-alone Choreography, has no way to show who the senders or receivers of the Message should be. A Choreography Task should be used instead.</td>
</tr>
</tbody>
</table>
| **Timer**: in Normal Flow     | Yes. Time is not precise in Choreography. It is established by the last visible Choreography Activity. The Participants involved in the Choreography Activity that immediately precedes will have a rough approximation of the time—there will be no exact synchronization.  

For relative timers: Only the Participants involved in the Choreography Activity that immediately precedes the Event would know the time. The sender of the Choreography Activity that immediately follows the timer must be involved in the Choreography Activity that immediately precedes the timer.  

For absolute timers (full time/date): All Participants would know the time. There does not have to be a relationship between the Participants of the Choreography Activities that are on either side the timer.  

The sender of the Choreography Activity that immediately follows the timer is the Participant that enforces the timer. |
<table>
<thead>
<tr>
<th><strong>Timer</strong>: Attached to Activity boundary</th>
<th><strong>Yes.</strong> Time is not exact in this case. It is established by the last visible Event. All <em>Participants</em> will have a rough approximation of the time—there will be no exact synchronization. This includes both interrupting and escalation Events. The <em>Participants</em> of the Choreography Activity that has the attached timer all enforce the timer. For relative timers: They all have to be involved in the Choreography Activity that immediately precedes the Activity with the attached timer. For absolute timers (full time/date): All <em>Participants</em> would know the time. They all have to be involved in the Choreography Activity that immediately precedes the Activity with the attached timer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Timer</strong>: Used in Event Gateway</td>
<td><strong>Yes.</strong> See Event-Based Gateway below.</td>
</tr>
<tr>
<td><strong>Error</strong>: Attached to Activity boundary</td>
<td><strong>No.</strong> An Error is only visible to a single <em>Participant</em>. That <em>Participant</em> will have to send a Message to the other <em>Participants</em>.</td>
</tr>
<tr>
<td><strong>Escalation</strong>: Used in Normal Flow</td>
<td></td>
</tr>
<tr>
<td><strong>Escalation</strong>: Attached to Activity boundary</td>
<td></td>
</tr>
<tr>
<td><strong>Cancel</strong>: in Normal Flow</td>
<td><strong>No.</strong> These are <em>Throw</em> Events. As with a Message Event, there would be no indicator as to who is the source of the <em>Cancel</em>.</td>
</tr>
<tr>
<td><strong>Cancel</strong>: Attached to Activity boundary</td>
<td><strong>Yes.</strong> These are <em>Catch</em> Events. As with a Message Event, they would be attached to the Choreography Activity on the Participant Band that is receiving the Cancel. These would only be interrupting Events.</td>
</tr>
<tr>
<td><strong>Compensation</strong>: in Normal Flow</td>
<td><strong>No.</strong> These are <em>Throw</em> Events. As with a Message, there would be no indicator as to who is the source of the <em>Cancel</em>.</td>
</tr>
<tr>
<td><strong>Compensation</strong>: Attached to Activity boundary</td>
<td><strong>Yes.</strong> These are <em>Catch</em> Events. As with a Message Event, they would be attached to the Choreography Activity on the Participant Band that is receiving the <em>Cancel</em>.</td>
</tr>
<tr>
<td><strong>Conditional</strong>: in Normal Flow</td>
<td><strong>Yes.</strong> This is a delay that waits for a change in data to trigger the Event. The data must be visible to the <em>Participants</em> as it was data of a previously sent Message.</td>
</tr>
<tr>
<td><strong>Conditional</strong>: Attached to Activity boundary</td>
<td><strong>Yes.</strong> This is an interruption that waits for a change in data to trigger the Event. The data must be visible to the <em>Participants</em> as it was data of a previously sent Message.</td>
</tr>
<tr>
<td><strong>Conditional</strong>: Used in Event Gateway</td>
<td><strong>Yes.</strong> This is a delay that waits for a change in data to trigger the Event. The data must be visible to the <em>Participants</em> as it was data of a previously sent Message.</td>
</tr>
<tr>
<td><strong>Link</strong>: in Normal Flow</td>
<td><strong>Yes.</strong> These types of Events merely create a virtual Sequence Flow. Thus, as long as a Sequence Flow between two elements is valid (and within a Choreography Process level), then a pair of Link Events can interrupt that Sequence Flow.</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Signal</strong>: in Normal Flow</td>
<td><strong>Yes.</strong> Only <em>Catch</em> Events can be used. For <em>Throw</em> Signal Events, there would be no indicator of who is the source <em>Participant.</em> This would be a delay in the Choreography that waits for the <em>Signal.</em> The source of the <em>Signal</em> is not required (and may not even be a <em>Participant</em> in the Choreography). There are no specific recipients of a <em>Signal.</em> All <em>Participants</em> of the Choreography (to comply) must be able to see the <em>Signal.</em></td>
</tr>
<tr>
<td><strong>Signal</strong>: Attached to Activity boundary</td>
<td><strong>Yes.</strong> These are <em>Catch</em> Events. This would be an interruption in the Choreography that waits for the <em>Signal.</em> The source of the <em>Signal</em> is not required (and may not even be a <em>Participant</em> in the Choreography). There are no specific recipients of a <em>Signal.</em> All <em>Participants</em> of the Choreography (to comply) must be able to see the <em>Signal.</em> This Event should not (must not?) be attached to a Participant Band or this would suggest that that <em>Participant</em> is a specific recipient of the <em>Signal.</em></td>
</tr>
<tr>
<td><strong>Signal</strong>: Used in Event Gateway</td>
<td><strong>Yes.</strong> These are <em>Catch</em> Events. This would be a delay in the Choreography that waits for the <em>Signal.</em> The source of the <em>Signal</em> is not required (and may not even be a <em>Participant</em> in the Choreography). There are no specific recipients of a <em>Signal.</em> All <em>Participants</em> of the Choreography (to comply) must be able to see the <em>Signal.</em></td>
</tr>
<tr>
<td><strong>Multiple</strong>: in Normal Flow</td>
<td><strong>Yes.</strong> But they can only be a collection of valid <em>Catch</em> Events. As in <em>Orchestration,</em> this acts like an OR. Any one of the incoming triggers will continue the Choreography.</td>
</tr>
<tr>
<td><strong>Multiple</strong>: Attached to Activity Boundary</td>
<td><strong>Yes.</strong> But they can only be a collection of valid <em>Catch</em> Events. As in <em>Orchestration,</em> this acts like an OR. Any one of the incoming triggers will interrupt the Choreography Activity.</td>
</tr>
</tbody>
</table>
12.5.3. End Events

End Events provide a graphical marker for the end of a path within the Choreography.

Table 12-8 – Use of End Events in Choreography

<table>
<thead>
<tr>
<th>Type of Event</th>
<th>Usage in Choreography?</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>None</strong></td>
<td><strong>Yes.</strong> This is really just a graphical marker since the sending of the previous Message in the Choreography is really the end of the Choreography. The Participants of the Choreography would understand that they would not expect any further Message at that point.</td>
</tr>
<tr>
<td><strong>Message</strong></td>
<td><strong>No.</strong> A Message End Event, in a stand-alone Choreography, has no way to show who the senders or receivers of the Message should be. A Choreography Task should be used instead. Thus, a None End Event should be used as a graphical marker for the “end” of the Choreography.</td>
</tr>
<tr>
<td><strong>Error</strong></td>
<td><strong>No.</strong> These are Throw Events and there would be no way to indicate the Participant that is the source of the Error.</td>
</tr>
<tr>
<td><strong>Escalation</strong></td>
<td><strong>No.</strong> These are Throw Events and there would be no way to indicate the Participant that is the source of the Escalation.</td>
</tr>
<tr>
<td><strong>Cancel</strong></td>
<td><strong>No.</strong> These are Throw Events. As with a Message Event, there would be no indicator as to who is the source of the Cancel.</td>
</tr>
<tr>
<td><strong>Compensation</strong></td>
<td><strong>No.</strong> These are Throw Events. As with a Message Event, there would be no indicator as to who is the source of the compensation.</td>
</tr>
<tr>
<td><strong>Signal</strong></td>
<td><strong>No.</strong> These are Throw Events. As with a Message Event, there would be no indicator as to who is the source of the Signal.</td>
</tr>
<tr>
<td><strong>Multiple</strong></td>
<td><strong>No.</strong> Since there are no valid End Event Results (Terminate doesn’t count) in Choreography, there cannot be multiple of them.</td>
</tr>
<tr>
<td><strong>Terminate</strong></td>
<td><strong>Yes.</strong> However, there would be no specific ability to terminate the Choreography, since there is no controlling system. In this case, all Participants in the Choreography would understand that when the Terminate End Event is reached (actually when the Message that precedes it occurs), then no further messages will be expected in the Choreography, even if there were parallel paths. The use of the Terminate End Event really only works when there are only two (2) Participants. If there are more than two (2) Participants, then any Participant that was not involved in the last Choreography Task would not necessarily know that the Terminate End Event had been reached.</td>
</tr>
</tbody>
</table>
12.6. Gateways

In an Orchestration Process, Gateways are used to create alternative and/or parallel paths for that Process. Choreography has the same requirement of alternative and parallel paths. That is, interactions between Participants may happen in sequence, in parallel, or through exclusive selection. While the paths of Choreography follow the same basic patterns as that of an Orchestration Process, the lack of a central mechanism to maintain data visibility, and that there is no central evaluation, there are constraints as to how the Gateways are used in conjunction with the Choreography Activities that precede and follow the Gateways. These constraints are an extension of the basic sequencing constraints that was defined on page 364. The six (6) sections that follow will define how the types of Gateways are used in Choreography.

12.6.1. Exclusive Gateway

Exclusive Gateways (Decisions) are used to create alternative paths within a Process or a Choreography. For details of how Exclusive Gateways are used within an Orchestration Process see page 298.

Exclusive Gateways are used in Choreography, but they are constrained by the lack of a central mechanism to store the data that will be used in the Condition expressions of the Gateway’s outgoing Sequence Flow. Choreographies may contain natural language descriptions of the Gateway’s Conditions to document the alternative paths of the Choreography (e.g., “large orders” will go down one path while “small orders” will go down another path), but such Choreographies would be underspecified and would not be enforceable. To create an enforceable Choreography, the Gateway Conditions must be formal Condition Expressions; however:

- The data used for Gateway Conditions MUST have been in a Message that was sent prior to (upstream from) the Gateway.
- More specifically, all Participants that are directly affected by the Gateway MUST have either sent or received the Message(s) that contained the data used in the Conditions.
- Furthermore, all these Participants MUST have the same understanding of the data. That is, the actual values of the data cannot selectively change after a Participant has seen a Message. Changes to data during the course of the Choreography MUST be visible to all the Participants affected by the Gateway.

These constraints ensure that the Participants in the Choreography understand the basis (the actual value of the data) for the decision behind the Gateway.

One (1) or more Participants will actually “control” the Gateway decision; that is, these Participants make the decision through the internal Orchestration Processes. The decision is manifested by the particular Message that occurs in the Choreography (after the Gateway). This Message is the initiating Message of a Choreography Activity that follows the Gateway. Thus, only the Participants that are the initiators of the Messages that follow the Gateway are the ones that control the decision. This means that:

- The initiating Participants of the Choreography Activities that follow the Gateway MUST have sent or received the Message that provided the data upon which the decision is made.
- The Message that provides the data for the Gateway MAY be in any Choreography Activity prior to the Gateway (i.e., it does not have to immediately precede Gateway).
Figure 12-34 – An example of the Exclusive Gateway

Figure 12-35 shows the Collaboration that demonstrates how the above Choreography that includes an Exclusive Gateway can be enforced.
Figure 12-35 – The relationship of Choreography Activity Participants across the sides of the Exclusive Gateway shown through a Collaboration

Usually, the initiators for the Choreography Activities that follow the Gateway will be the same Participant. That is, there is only one (1) Participant controlling the decision. Often, the receivers of the initiating Message for those Choreography Activities will be the same Participant. However, it is possible that there could be different Participants receiving the initiating Message for each Choreography Activity (see Figure 12-36).
This configuration can only be valid if all the Participants in the Choreography Activities that follow the Gateway have seen the data upon which the decision is made. If either “Participant B” or “Participant C” had not sent or receive a Message with the appropriate data, then that Participant would not be able to know if they are suppose to receive a Message at that point in the Choreography. There is also the assumption that the value of the data is consistent from the point of view of all Participants.

Figure 12-37 displays the corresponding Collaboration view of the above Choreography Exclusive Gateway configuration.
Figure 12-37 – The corresponding Collaboration view of the above Choreography Exclusive Gateway configuration

The required execution behavior of the Gateway and associated Choreography Activities are enforced through the Business Processes of the Participants as follows:

- Each Choreography Activity and the Sequence Flow connections are reflected in each Participant Process.
- The Gateway is reflected in the Process of each Participant Process that is an initiator of Choreography Activities that follow the Gateway.
- For the receivers in Choreography Activities that follow the Gateway, an Event-Based Gateway is used to consume the associated Message (sent as an outcome of the Gateway). When
a Participant is the receiver of more than one of the alternative Messages, the corresponding receives follow the Event-Based Gateway. If the Participant is the receiver of only one such Message, that is also consumed through a receive following the Event-Based Gateway. This is because the Participant Process does not know whether it will receive a Message (since the Gateway entails a choice of outcomes).

12.6.2. Event-Based Gateway

As described above, the Event-Based Gateway represents a branching point in the Process where the alternatives are based on Events that occur at that point in the Process, rather than the evaluation of expressions using Process data. For details of how Event-Based Gateways are used within an Orchestration Process see Section “Event-Based Gateway” on page 307.

These Gateways are used in Choreography when the data used to make the decision is only visible to the internal Processes of one Participant. That is, there has been no Message sent within the Choreography that would expose the data used to make the decision. Thus, the only way that the other Participants can be aware of the results of the decision is by the particular Message that arrives next.

- On the right side of the Gateway: either
  - The senders MUST to be the same; or
  - The receivers MUST to be the same
    - After the first Choreography Activity occurs, the other Choreography Activities for the Gateway MUST NOT occur.
- Message Intermediate Events MUST NOT be used in the Event-Based Gateway.
- Timer Intermediate Events MAY be used, but they restrict the participation in the Gateway.
  - For relative timers: All Participants on the right side of the Gateway MUST be involved in the Choreography Activity that immediately precedes the Gateway.
  - For absolute timers (full time/date): All Participants on the right side of the Gateway MUST be involved in the Choreography Activity that immediately precedes the Gateway.
- Signal Intermediate Events MAY be used (they are visible to all Participants)
- No other types of Intermediate Events are allowed.
Figure 12-38 – An example of an Event Gateway

Figure 12-39 displays the corresponding Collaboration view of the above Choreography Event Gateway configuration.
The required execution behavior of the Event-Based Gateway and associated Choreography Activities are enforced through the Business Processes of the Participants as follows:

- Each Choreography Activity and the Sequence Flow connections is reflected in each Participant Process.
- If the senders following the Gateway are the same, the Event-Based Gateway is reflected as an Exclusive Gateway in that Participant’s Process. This is because the choice of which Message to send is determined by the same Participant. If the senders are different, sending occurs through different Processes.
- If the receivers are the same, the senders can be the same or different. In this case, the Event-Based Gateway is reflected in the receiver’s Process, with the different Message receives following the Gateway.
- If the receivers are different, the senders need to be the same. The Event-Based Gateway is reflected for different receiver Processes such that the respective receive follows the Gateway. A time-out may be used to ensure that the Gateway does not wait indefinitely.
12.6.3. Inclusive Gateway

Inclusive Gateways are used for modeling points of synchronization of a number of branches, not all of which are active, after which one or more alternative branches are chosen within a Choreography flow. For example, one of more branches may be activated upstream, in parallel, depending on the nature of goods in an order (e.g. large orders, fragile goods orders, orders belonging to pre-existing shipment contracts), and these are subsequently merged. The point of merge results in one or more risk mitigating outcomes (e.g. special insurance protection needed, special packaging needed, and different container categories needed). Inclusive Gateways are also used within an Orchestration Process see page 300.

Like Exclusive Gateways, Inclusive Gateways are used in a Choreography, but they are constrained by the lack of a central mechanism to store the data that will be used in the Condition expressions of the Gateway’s outgoing Sequence Flows. Choreographies may contain natural language descriptions of the Gateway’s Conditions to document the one more alternative paths of the Choreography (e.g., “special insurance protection needed”, “special packaging needed”, and different “container category needed”), but such Choreographies would be underspecified and would not be enforceable. To create an enforceable Choreography, the Gateway Conditions must be formal Condition Expressions. In general the following rules apply for the Expressions:

Like the enforceability of the Exclusive Gateway, the Inclusive Gateway in a Choreography requires that the data in the Expressions of the outgoing Sequence Flow of the Gateway be available to the initiators of the Choreography Activities of outgoing Sequence Flow. This means that the initiators of these Choreography Activities should also be senders or receivers of Messages in Choreography Activities immediately preceding the Gateway. The major difference, however, is that the synchronizing behavior of the Inclusive Gateway can only be enforced through one participant. Hence, the rules for enforceability are as follows:

- The data used for Gateway Conditions MUST have been in a Message that was sent prior to (upstream from) the Gateway.
- More specifically, all Participants that are directly affected by the Gateway MUST have either sent or received the Message(s) that contained the data used in the Conditions.
- Furthermore, all these Participants MUST have the same understanding of the data. That is, the actual values of the data cannot selectively change after a Participant has seen a Message. Changes to data during the course of the Choreography MUST be visible to all the Participants affected by the Gateway.
- Merge: In order to enforce the synchronizing merge of the Gateway, the senders or receivers Choreography Activities preceding the Gateway need to be the same Participant. This ensures that the merge can be enforced. (This relies on the assumption of logical atomicity of a Choreography Activity, otherwise the rule would require that all receivers are the same so that the Gateway is enforced in the receiver’s Process only).
- Split: In order to enforce the split side of the Gateway, the initiators of all Choreography Activities immediately following the Gateway must be the same as the common sender or receiver of Choreography Activities preceding the Gateway. The sender(s) of all the Choreography Activities after the Gateway must be involved in all the Choreography Activities that immediately precede the Gateway.

Figure 12-40 shows an example of a Choreography with an Inclusive Gateway. The Gateway is enforced in the corresponding Business Processes of the Participants involved. For the merge behavior to
be enforced, the receivers of Choreography Activities preceding the Gateway and the initiator of Choreography Activities immediately following the Gateway are the same Participant (i.e. B).

Figure 12-40 – An example of a Choreography Inclusive Gateway configuration
Figure 12-41 – The corresponding Collaboration view of the above Choreography Inclusive Gateway configuration

Figure 12-42, a variation of Figure 12-40 above, shows an example of a Choreography illustrating the enforcement of the split behavior of the Inclusive Gateway. For the split behavior to be enforced, the initiators of Choreography Activities immediately following the Gateway and the receiver of Choreography Activities immediately preceding the Gateway are the same Participant (i.e. A).
Figure 12-42 – An example of a Choreography Inclusive Gateway configuration
Figure 12-43 – The corresponding Collaboration view of the above Choreography Inclusive Gateway configuration
Figure 12-44 – Another example of a Choreography Inclusive Gateway configuration
Figure 12-45 – The corresponding Collaboration view of the above Choreography Inclusive Gateway configuration

12.6.4. Parallel Gateway

Parallel Gateways are used to create paths and are performed at the same time, within a Choreography flow. For details of how Parallel Gateways are used within an Orchestration Process see page 302.
Since there is no conditionality for these Gateways, they are available as-is in Choreography. They create parallel paths of the Choreography that all Participants are aware of.

- The sender(s) of all the Activities after the Gateway must be involved in all the Activities that immediately precede the Gateway.
- If there is a chain of Gateways with no Choreography Activities in between, the Choreography Activity that precedes the chain satisfies the above constraint.

Figure 12-46 shows the relationship of Choreography Activity Participants across the sides of the Parallel Gateway.

![Parallel Gateway Diagram]

Figure 12-46 – The relationship of Choreography Activity Participants across the sides of the Parallel Gateway

Figure 12-47 shows the corresponding Collaboration view of the above Choreography Parallel Gateway configuration.
The required execution behavior of the Parallel Gateway and associated Choreography Activities are enforced through the Business Processes of the Participants as follows:

- Each Choreography Activity and the Sequence Flow connections is reflected in each Participant Process.
- If the senders following the Parallel Gateway are the same, a Parallel Gateway is reflected in the sender’s Process followed by Message sending actions to the corresponding receivers.
- If the senders are different, the Parallel Gateway is manifested by Sequence Flows followed by the sending action in each Process.
### 12.6.5. Complex Gateway

Complex Gateways can model partial merges in Business Processes where when some but not all of a set of preceding branches complete, the Gateway fires. This can be considered the discriminator/n-of-m join pattern and is not supported through the inclusive OR merge since it is not concerned with sets of branches, but rather branches which have tokens. Applied in Choreographies, Complex Gateways can model tendering and information canvassing use cases where requests are sent to participants who respond at different times.

Consider an e-tender which sends a request for quote to service providers (e.g. warehouse storage) in a marketplace. The e-tender Process sends out each request and anticipates a response through two Choreography Activities with a sequential flow between these. The request-response branches merge at a Complex Gateway to model the requirement that when 60% responses have arrived, an assessment of the tender can proceed. The assessment occurs after the Complex Gateway. If the assessment reports that the reserve amount indicated by the customer cannot be met, a new iteration of the tender is made. All up a maximum of 3 tenders is run. A key issue is to ensure that the responses should not be mixed across tender iterations.

![Figure 12-48 – An example of a Choreography Complex Gateway configuration](image)

---

12.6.6. Chaining Gateways

It is possible to chain Gateways. This means that a modeler can sequence two (2) or more Gateways without any intervening Choreography Activities, however the constraints on what participants can appear before and after the chain must be observed.
12.7. Choreography within Collaboration

Participants

Participants are used in both Collaborations and Choreographies.

Swimlanes

Swimlanes, both Pools and Lanes, are not used in Choreographies. Pools are used exclusively in Collaborations (see page 46). Participants, which can be associated to Pools, however, are used in the Participant Bands of Choreography Tasks (see page 350) and Choreography Sub-Processes (see page 356). Pools can be used with Choreography diagrams when in the context of a Collaboration diagram (see page 394).

Lanes are not used in Choreography diagrams since Lanes are sub-partitions of a Pool and Choreographies are placed in between the Pools (if used in a Collaboration).

Figure 12-50 shows an example of a Choreography Process combined with Black Box Pools.

Figure 12-50 – An example of a Choreography Process combined with Black Box Pools
Figure 12-51 shows an example of a Choreography Process combined with Pools that contain Processes.

13. BPMN Notation and Diagrams

13.1. Diagram Interchange

The goal of the Diagram Interchange (DI) metamodel is to provide a way for BPMN to persist and interchange diagrams. Having common interchange format benefits tool interoperability, which is an ever increasing demand by end users. The DI metamodel, similar to the BPMN semantic metamodel, is defined as a MOF-based metamodel and hence its instances are serialized and interchanged with XMI.

Annex B is a non-normative description of the generic diagram interchange mechanism that was applied to BPMN 2.0 in order to derive BPMN 2.0’s normative diagram interchange specification. The normative BPMN 2.0 diagram interchange specification has two parts. One part is this Chapter 13 of this document. The other part is document <omg document #>, which contains the diagram interchange schema. Section 13.2 of this document defines an instance of a metamodel that is defined in Annex B.

13.2. BPMN Diagram Definition Library

This chapter describes the BPMN diagram definition (M1) library. View definitions contained in this library define views that constitute the building blocks of BPMN diagrams.

13.2.1. BPMN Diagram Definitions

The BPMN 2.0 specification defines the following types of diagrams: Orchestration diagram (aka Process diagram), Collaboration diagram, Conversation diagram and Choreography diagram. All of these are described in detail in Sections 9, 10, 11 and 12.

![Figure 13-1 – BPMN Diagram Definitions](image-url)
BPMNDiagram

BPMNDiagram is an abstract DiagramDefinition that is the super definition of all BPMN diagram definitions. BPMNDiagram has no further relationships or constraints.

ProcessDiagram

ProcessDiagram is a concrete DiagramDefinition that defines diagrams that reference a BPMN Process element as a context.

Super Definition

- BPMNDiagram

Context Type

- Process

Child Definitions

Table 13-1 – ProcessDiagram children

<td>Specifies the width of the compartment. Default is auto size (-1)</td>
</tr>
<tr>
<td><code>height</code>: Integer = -1</td>
<td>Specifies the height of the compartment. Default is auto size (-1)</td>
</tr>
<tr>
<td><code>x</code>: Integer = -1</td>
<td>Specifies the x position of the Node relative to the Node owning/containing the Node</td>
</tr>
<tr>
<td><code>y</code>: Integer = -1</td>
<td>Specifies the y position of Node relative to the Node owning/containing the Node</td>
</tr>
</tbody>
</table>

#### 13.2.3. BPMN Compartment Definitions

Every one of the diagram definitions described in the previous section contains different areas which contain and visualize certain parts of the overall BPMN diagram. These areas all called “compartments”. The BPMN 2.0
spec defines three types of these compartments which are *Lanes*, *Pools* and *Choreographies*. For more detailed information see Sections 9.2 and 9.4.

**Figure 13-2 – BPMN Compartment Definitions**

**BPMNCompartment**

BPMNCompartment is an abstract BPMNNodeDefinition that is the super definition for all BPMN compartment types, like *Lanes*, *Pools* and *Choreography*. A compartment visually partitions a diagram by grouping some shapes in a bounded area.

**Super Definition**

- BPMNNode

**Style Definitions**

**Table 13-6 – BPMNCompartment styles**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isVisible: Boolean = true</td>
<td>Whether a compartment is visible or hidden (still preserved in the model but not shown)</td>
</tr>
</tbody>
</table>
PoolCompartment

PoolCompartment is a concrete NodeDefinition that defines the visual element of a BPMN Pool. A Pool is the graphical representation of a Participant in a Collaboration (see page 46). It is also acts as a graphical container for partitioning a set of Activities from other Pools, usually in the context of B2B situations.

![Figure 13-3 – A Pool](image)

Super Definition

<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>lanes: LaneCompartment [1..*]</td>
<td>A reference to all the lane elements contained in that pool.</td>
</tr>
</tbody>
</table>

LaneCompartment

LaneCompartment is a concrete NodeDefinition that defines the visual element of a BPMN lane. A Lane is a sub-partition within a Pool and will extend the entire length of the Pool, either vertically or horizontally (see on page 49). Lanes are used to organize and categorize Activities.

![Figure 13-4 – Lanes within a Pool](image)

Super Definition

- BPMNCompartment

Context Type

- Lane
Child Definitions

</thead>
<tbody>
<tr>
<td>shape: BPMNShape [0..*]</td>
<td>The BPMN shapes displayed inside the Choreography area.</td>
</tr>
</tbody>
</table>

13.2.4. BPMN Connectors

The BPMN 2.0 specification defines different elements for connecting BPMN elements. These are mainly Sequence Flow connectors, Message Flow connectors, Association connectors, and Data Association connectors.
**Figure 13-5 – BPMN Connectors class diagram**

**BPMNConnector**

BPMNConnector is an abstract `ConnectorDefinition` that defines the visual line connecting BPMN nodes.

**Super Definition**

- `ConnectorDefinition`

**Child Definitions**

**Table 13-10 – BPMNConnector children**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>

<td>A reference to the Node element which is the target of the connector</td>
</tr>
<tr>
<td><strong>connectorLabel: BPMNLabel [0..1]</strong></td>
<td>The optional label for the Connector</td>
</tr>
</tbody>
</table>
**SequenceFlowConnector**

A Sequence Flow is used to show the order that Activities will be performed in a Process (see page 159) and in a Choreography (see page 348).

**Figure 13-6 – A Sequence Flow**

SequenceFlowConnector is a concrete BPMNConnector that defines the visual line representing a BPMN Sequence Flow connector.

**Super Definition**
- BPMNConnector

**Context Type**
- Sequence Flow

**DataAssociationConnector**

A Data Association is used to model a data flow between Data Objects and Activities or Events.

**Figure 13-7 – A Data Association**

DataAssociationConnector is a concrete BPMNConnector that defines the visual line representing a BPMN Data Association flow connector.

**Super Definition**
- BPMNConnector

**Context Type**
- Data Association

**MessageFlowConnector**

A Message Flow is used to show the flow of Messages between two Participants that are prepared to send and receive them (see page 119). In BPMN, two separate Pools in a Collaboration Diagram will represent the two Participants (e.g., business PartnerEntities or business PartnerRoles).

**Figure 13-8 – A Message Flow**
MessageFlowConnector is a concrete BPMNConnector that defines the visual line representing a BPMN Message Flow connector.

**Super Definition**
- BPMNConnector

**Context Type**
- Message Flow

**AssociationConnector**

An **Association** is used to link information and Artifacts with BPMN graphical elements (see page 88). Text Annotations (see page 53) and other Artifacts (see page 66) can be associated with the graphical elements. An arrowhead on the **Association** indicates a direction of flow (e.g., data), when appropriate.

---

**Figure 13-9 – Associations**

AssociationConnector is a concrete BPMNConnector that defines the visual line representing a BPMN Association connector.

**Super Definition**
- BPMNConnector

**Context Type**
- Association

**CompensationFlowConnector**

*Compensation Association* occurs outside the normal flow of the Process and is based upon an Event (a Compensation Intermediate Event) that is triggered through the failure of a transaction or a Compensate Event (see page 270). The target of the Association must be marked as a Compensation Activity.
Figure 13-10 – Compensation Flow from a Compensation Intermediate Event

CompensationFlowConnector is a concrete BPMNConnector that defines the visual line representing a BPMN Association connector.

Super Definition
- BPMNConnector

Context Type
- Association

ConversationLinkConnector

ConversationLinkConnector is a concrete BPMNConnector that defines the visual line representing a BPMN ConversationLink connector.

Super Definition
- BPMNConnector

Context Type
- ConversationLink

13.2.5. BPMN Shapes

The BPMN 2.0 specification describes different flow shapes, like Activities, Data Objects, or Text Annotations. These shape elements are contained in the corresponding BPMN diagram element and can be referenced by the BPMN-DI element LaneCompartment and ChoreographyCompartment. The position of a shape is relative to the visual owner, LaneCompartment or ChoreographyCompartment.

Figure 13-11 – BPMN Shapes class diagram

BPMNShape is an abstract BPMNNode.
Super Definition

- BPMNConnector

**ActivityShape**

The element ActivityShape represents an Activity contained in a Process model. It extends the FlowNodeShape element. The type Activity is determined by the referenced semantic meta model element.

An Activity is a generic term for work that company performs (see page 159 in Process. An Activity can be atomic or non-atomic (compound). The types of Activities that are a part of a Process model are: Sub-Process and Task, which are rounded rectangles. Activities are used in both standard Processes and in Choreographies.

![Figure 13-12 – An Activity](image)

ActivityShape is a concrete BPMNShape.

Super Definition

- BPMNShape

Context Type

- Activity

**GatewayShape**

A Gateway is used to control the divergence and convergence of Sequence Flow in a Process (see page 159) and in a Choreography (see page 375). Thus, it will determine branching, forking, merging, and joining of paths. Internal markers will indicate the type of behavior control.

![Figure 13-13 – A Gateway](image)

GatewayShape is a concrete BPMNShape.
Super Definition

- BPMNShape

Context Type

- Gateway

EventShape

An Event is something that “happens” during the course of a Process (see page 53) or a Choreography (see page 369). These Events affect the flow of the model and usually have a cause (Trigger) or an impact (Result). Events are circles with open centers to allow internal markers to differentiate different Triggers or Results. There are three types of Events, based on when they affect the flow: Start, Intermediate, and End.

Figure 13-15 – An Event

EventShape is a concrete BPMNShape
Super Definition

- BPMNShape

Context Type

**ChoreographyActivityShape**

A Choreography Task is an atomic Activity in a Choreography (see page 350). It represents a set of one (1) or more Message exchanges. Each Choreography Task involves two (2) or more Participants. The name of the Choreography Task and each of the Participants are all displayed in the different bands that make up the shape’s graphical notation. There are two (2) more Participant Bands and one Task Name Band.

14. BPMN Execution Semantics

Note: The content of this chapter is required for BPMN Process Execution Conformance or for BPMN Complete Conformance. However, this chapter is not required for BPMN Process Modeling Conformance, BPMN Choreography Conformance, or BPMN BPEL Process Execution Conformance. For more information about BPMN conformance types, see page 28.

This section defines the execution semantics for orchestrations in BPMN 2.0. The purpose of this execution semantics is to describe a clear and precise understanding of the operation of the elements. However, for some elements only conceptual model is provided which does not specify details needed to execute them on an engine. These elements are called non-operational. Implementations MAY extend the semantics of non-operational elements to make them executable, but this is considered to be an optional extension to BPMN. Non-operational elements MAY be ignored by implementations conforming to BPMN Process Execution Conformance type. The following elements are non-operational:

- Manual Task
- Abstract Task
- DataState
- IORules
- Ad-Hoc Process
- ItemDefinitions with an itemKind of Physical
- the inputSetWithWhileExecuting attribute of DataInput
- the outputSetWithWhileExecuting attribute of DataOutput
- the isClosed attribute of Process
- the isImmediate attribute of Sequence Flow

The execution semantics are described informally (textually), and this based on prior research involving the formalization of execution semantics using mathematical formalisms.

This section provides the execution semantics of elements through the following structure:

- A description of the operational semantics of the element,
- Exception issues for the element where relevant,
- List of workflow patterns supported by the element where relevant.

---

Proposal for:
Business Process Model and Notation (BPMN), v2.0
14.1. Process Instantiation and Termination

A Process is instantiated when one of its Start Events occurs. Each occurrence of a Start Event creates a new Process Instance unless the Start Event participates in a Conversation that includes other Start Events. In that case, a new Process instance is only created if none already exists for the specific Conversation (identified through its associated correlation information) of the Event occurrence. Subsequent Start Events that share the same correlation information as a Start Event that created a Process instance are routed to that Process instance. Note that a global Process must neither have any empty Start Event nor any Gateway or Activity without incoming Sequence Flow. An exception is the Event Gateway.

A Process can also be started via an Event-Based Gateway that has no incoming Sequence Flow and its Instantiate flag is true. If the Event-Based Gateway is exclusive, the first matching Event will create a new instance of the Process. The Process then does not wait for the other Events originating from the same Event-Based Gateway (see also semantics of the Event-Based Exclusive Gateway on page 437). If the Event-Based Gateway is parallel, also the first matching Event creates a new Process instance. However, the Process then waits for the other Events to arrive. As stated above, those Events must have the same correlation information as the Event that arrived first. A Process instance completes only if all Events that succeed a Parallel Event-Based Gateway have occurred.

To specify that the instantiation of a Process waits for multiple Start Events to happen, a Multiple Parallel Start Event can be used.

Note that two Start Events are alternative, A Process instance triggered by one (1) of the Start Events does not wait for an alternative Start Event to occur. Note that there may be multiple instantiating Parallel Event-Based Gateways. This allows the modeler to express that either all the Events after the first Gateway occur or all the Events after the second Gateway and so forth.

Each Start Event that occurs creates a token on its outgoing Sequence Flow, which is followed as described by the semantics of the other Process elements.

A Process instance is completed, if and only if the following three conditions hold:

- If the instance was created through an instantiating Parallel Gateway, then all subsequent Events (of that Gateway) must have occurred.
- There is no token remaining within the Process instance.
- No Activity of the Process is still active.

For a Process instance to become completed, all Tokens in that instance must reach an end node, i.e., a node without outgoing Sequence Flow. A Token reaching an End Event triggers the behavior associated with the Event type is, e.g., the associated Message is sent for a Message End Event, the associated Signal is sent for a Signal End Event, and so on. If a Token reaches a Terminate End Event, the entire Process is abnormally terminated.

14.2. Activities

This section specifies the semantics of Activities. First the semantics that is common to all Activities is described. Subsequently the semantics of special types of Activities is described.
14.2.1. Sequence Flow Considerations

The nature and behavior of Sequence Flow is described in Section 8.3.17. But there are special considerations relative to Sequence Flow when applied to Activities. An Activity that is the target of multiple Sequence Flow participates in “uncontrolled flow.”

To facilitate the definition of Sequence Flow (and other Process elements) behavior, we employ the concept of a token that will traverse the Sequence Flow and pass through the elements in the Process. A token is a theoretical concept that is used as an aid to define the behavior of a Process that is being performed. The behavior of Process elements can be defined by describing how they interact with a token as it “traverses” the structure of the Process. However, modeling and execution tools that implement BPMN are not required to implement any form of token.

Uncontrolled flow means that, for each Token arriving on any incoming Sequence Flow into the Activity, the Task will be enabled independently of the arrival of Tokens on other incoming Sequence Flow. The presence of multiple incoming Sequence Flow behaves as an exclusive gateway. If the flow of Tokens into the Task needs to be ‘controlled’, then Gateways (other than Exclusive) should be explicitly included in the Process flow prior to the Task to fully eliminate semantic ambiguities.

If an Activity has no incoming Sequence Flow, and there are no Start Events in the containing Process or Sub-Process, the Activity will be instantiated when the containing Process or Sub-Process is instantiated. Exceptions to this are Event Sub-Processes and Activities marked as Compensation Activities, as they have specialized instantiation behavior.

Activities can also be source of Sequence Flow. If an Activity has multiple outgoing Sequence Flow, all of them will receive a token when the Activity transitions to the Completed state. Semantics for token propagation for other termination states is defined below. Thus, multiple outgoing Sequence Flow behaves as a parallel split. Multiple outgoing Sequence Flow with conditions behaves as an inclusive split. A mix of multiple outgoing Sequence Flow with and without conditions is considered as a combination of a parallel and an inclusive split as shown in the following figure.

![Figure 14-1 – Behavior of multiple outgoing sequence flow of an Activity](image)

If the Activity has no outgoing Sequence Flow and there are no End Events in the containing Process or Sub-Process, the Activity will terminate and termination semantics for the container applied.

Token movement across a Sequence Flow does not have any timing constraints. A token might take a long or short time to move across the Sequence Flow. If the isImmediate attribute of a Sequence Flow has a value of false, or has no value and is taken to mean false, then Activities not in the model MAY be executed while the token is moving along the Sequence Flow. If the isImmediate attribute of a Sequence Flow has a value of true, or has no value and is taken to mean true, then Activities not in the model MAY NOT be executed while the token is moving along the Sequence Flow.
14.2.2. Activity

An Activity is a Process step that can be atomic (Tasks) or decomposable (Sub-Processes) and is executed by either a system (automated) or humans (manual). All Activities share common attributes and behavior such as states and state transitions. An Activity, regardless of type, has lifecycle generally characterizing its operational semantics. The lifecycle, described as a UML state diagram in Figure 14-2, entails states and transitions between the states.
The lifecycle of an Activity is described as follows:

**Figure 14-2 – The Lifecycle of a BPMN Activity**
An Activity is *Ready* for execution if the required number of *Tokens* is available to activate the Activity. The required number of Tokens (one or more) is indicated by the attribute *StartQuantity*. If the Activity has more than one *Incoming Sequence Flow*, there is an implied Exclusive Gateway that defines the behavior.

When some data InputSet becomes available, the Activity changes from *Ready* to the *Active* state. The availability of a data InputSet is evaluated as follows. The data InputSets are evaluated in order. For each InputSet, the data inputs are filled with data coming from the elements of the context such as Data Objects or Properties by triggering the input Data Associations. An InputSet is available if each of its required data inputs is available. A data input is required by a data InputSet if it is not optional in that InputSet. If an InputSet is available, it is used to start the Activity. Further InputSets are not evaluated. If an InputSet is not available, the next InputSet is evaluated. The Activity waits until one InputSet becomes available.

An Activity, if *Ready* or *Active*, can be Withdrawn from being able to complete in the context of a race condition. This situation occurs for Tasks that are attached after an Event-Based Exclusive Gateway. The first element (Task or Event) that completes causes all other Tasks to be withdrawn.

If an Activity fails during execution, it changes from the state *Active* to *Failed*.

- If a fault happens in the environment of the Activity, termination of the Activity is triggered, causing the Activity to go into the state *Terminated*.

If an Activity’s execution ends without anomalies, the Activity’s state changes to *Completing*. This intermediate state caters for processing steps prior to completion of the Activity. An example of where this is useful is when non-interrupting Event Handlers (proposed for BPMN 2.0) are attached to an Activity. They need to complete before the Activity to which it is attached can complete. The state *Completing* of the main Activity indicates that the execution of the main Activity has been completed, however, the main Activity is not allowed to be in the state *Completed*, as it still has to wait for all non-interrupting Event Handlers to complete. The state Completing does not allow further processing steps, otherwise allowed during the execution of the Activity. For example, new attached non-interrupting Event Handlers may be created as long as the main Activity is in state *Active*. However, once in the state *Completing*, running handlers should be completed with no possibility to create new ones.

After all completion dependencies have been fulfilled, the state of the Activity changes to *Completed*. The outgoing Sequence Flow becomes active and a number of Tokens, indicated by the attribute *CompletionQuantity*, is placed on it. If there is more than one (1) outbound Sequence Flow for an Activity, it behaves like an implicit Parallel Gateway. Upon completion, also a data OutputSet of the Activity is selected as follows. All OutputSets are checked for availability in order. An OutputSet is available if all its required data outputs are available. A data output is required by an OutputSet if it is not optional in that OutputSet. If the data OutputSet is available, data is pushed into the context of the Activity by triggering the output Data Associations of all its data outputs. Further OutputSets are not evaluated. If the data OutputSet is not available, the next data OutputSet is checked. If no OutputSet is available, a runtime exception is thrown. If the Activity has an associated IORule, the chosen OutputSet is checked against that IORule, i.e., it is checked whether the InputSet that was used in starting the Activity instance is together with the chosen OutputSet compliant with the IORule. If not, a runtime exception is thrown.

Only completed Activities could, in principle, be compensated, however, the Activity can end in state *Completed*, as compensation might not be triggered or there might be no compensation handler specified. If the compensation handler is invoked, the Activity changes to state *Compensating* until
either compensation finishes successfully (state Compensated), an exceptions occurs (state Failed) or controlled or uncontrolled termination is triggered (state Terminated).

14.2.3. Task

Task execution and completion for the different Task types are as follows:

- **Service Task**: Upon instantiation, the associated service is invoked. On completion of the service, the Service Task completes. If the invoked service returns a fault, that fault is treated as interrupting error, and the Activity fails.
- **Send Task**: Upon instantiation, the associated Message is sent and the Send Task completes.
- **Receive Task**: Upon instantiation, the Receive Task begins waiting for the associated Message. When the Message arrives, the Receive Task completes.
- **User Task**: Upon instantiation, the User Task is distributed to the assigned person or group of people. When the work has been done, the User Task completes.
- **Manual Task**: Upon instantiation, the manual task is distributed to the assigned person or group of people. When the work has been done, the Manual Task completes. This is a conceptual model only; a Manual Task is never actually executed by an IT system.
- **Business Rule Task**: Upon instantiation, the associated business rule is called. On completion of the business rule, the Business Rule Task completes.
- **Script Task**: Upon instantiation, the associated script is invoked. On completion of the script, the Script Task completes.
- **Abstract Task**: Upon instantiation, the Abstract Task completes. This is a conceptual model only; an Abstract Task is never actually executed by an IT system.

14.2.4. Sub-Process/Call Activity

A Sub-Process is an Activity which encapsulates a Process which is in turn modeled by Activities, Gateways, Events and Sequence Flow. Once a Sub-Process is instantiated, its elements behave as in a normal Process. The instantiation and completion of a Sub-Process is defined as follows:

- A Sub-Process is instantiated when it is reached by a Sequence Flow token. The Sub-Process has either a unique empty Start Event, which gets a token upon instantiation, or it has no Start Event but Activities and Gateways without incoming Sequence Flow. In the latter case all such Activities and Gateways get a token. A Sub-Process must not have any non-empty Start Events.
- If the Sub-Process does not have incoming Sequence Flow but Start Events that are target of Sequence Flow from outside the Sub-Process, the Sub-Process is instantiated when one of these Start Events is reached by a token. Multiple such Start Events are alternative, i.e., each such Start Event that is reached by a token generates a new instance.
- A Sub-Process instance completes when there are no more tokens in the Sub-Process and none of its Activities is still active.
- If a “terminate” End Event is reached, the Sub-Process is abnormally terminated. For a “cancel” End Event, the Sub-Process is abnormally terminated and the associated Transaction is aborted.
Control leaves the Sub-Process through a cancel intermediate boundary Event. For all other End Events, the behavior associated with the Event type is performed, e.g., the associated Message is sent for a Message End Event, the associated signal is sent for a signal End Event, and so on.

- If a global Process is called through a Call Activity, then the Call Activity has the same instantiation and termination semantics as a Sub-Process. However, in contrast to a Sub-Process, the global Process that is called may also have non-empty Start Events. These non-empty Start Events are alternative to the empty Start Event and hence they are ignored when the Process is called from another Process.

### 14.2.5. Ad-Hoc Sub-Process

An Ad-Hoc Sub-Process or Process contains a number of embedded inner Activities and is intended to be executed with a more flexible ordering compared to the typical routing of Processes. Unlike regular Processes, it does not contain a complete, structured BPMN diagram description—i.e., from Start Event to End Event. Instead the Ad-Hoc Sub-Process contains only Activities, Sequence Flow, Gateways, and Intermediate Events. An Ad-Hoc Sub-Process may also contain Data Objects and Data Associations. The Activities within the Ad-Hoc Sub-Process are not required to have incoming and outgoing Sequence Flow. However, it is possible to specify Sequence Flow between some of the contained Activities. When used, Sequence Flow will provide the same ordering constraints as in a regular Process. To have any meaning, Intermediate Events will have an outgoing Sequence Flow and they can be triggered multiple times while the Ad-Hoc Sub-Process is active.

The contained Activities are executed sequentially or in parallel, they can be executed multiple times in an order that is only constrained through the specified Sequence Flow, Gateways, and data connections.

**Operational semantics:**

- At any point in time, a subset of the embedded Activities is enabled. Initially, all Activities without incoming Sequence Flow are enabled. One of the enabled Activities is selected for execution. This is not done by the implementation but usually by a Human Performer. If the ordering attribute is set to sequential, another enabled Activity can be selected for execution only if the previous one has terminated. If the ordering attribute is set to parallel, another enabled Activity can be selected for execution at any time. This implies the possibility of the multiple parallel instances of the same inner Activity.

- After each completion of an inner Activity, a condition specified through the completionCondition attribute is evaluated:
  - If false, the set of enabled inner Activities is updated and new Activities can be selected for execution.
  - If true, the Ad-Hoc Sub-Process completes without executing further inner Activities. In case the ordering attribute is set to parallel and the attribute cancelRemainingInstances is true, running instances of inner Activities are canceled. If cancelRemainingInstances is set to false, the Ad-Hoc Sub-Process completes after all remaining inner instances have completed or terminated.

- When an inner Activity with outgoing Sequence Flow completes, a number of tokens are produced on its outgoing Sequence Flow. This number is specified through its attribute completionQuantity. The resulting state may contain also other tokens on incoming Sequence Flow of either Activities, converging Parallel or Complex Gateways, or an Intermediate
Event. Then all tokens are propagated as far as possible, i.e., all activated Gateways are executed until no Gateway and Intermediate Event is activated anymore. Consequently, a state is obtained where each token is on an incoming Sequence Flow of either an inner Activity, a converging Parallel or Complex Gateway or an Intermediate Event. An inner Activity is now enabled if it has either no incoming Sequence Flow or there are sufficiently many tokens on its incoming Sequence Flow (as specified through startQuantity).

Workflow patterns: WCP-17 Interleaved parallel routing.

14.2.6. Loop Activity

The Loop Activity is a type of Activity that acts as a wrapper for an inner Activity that can be executed multiple times in sequence.

Operational semantics: Attributes can be set to determine the behavior. The Loop Activity executes the inner Activity as long as the loopCondition evaluates to true. A testBefore attribute is set to decide when the loopCondition should be evaluated: either before the Activity is executed or after, corresponding to a pre- and post-tested loop respectively. A loopMaximum attribute can be set to specify a maximal number of iterations. If it is not set, the number is unbounded.

Workflow Patterns Support: WCP-21 Structured Loop.

14.2.7. Multiple Instances Activity

The multi-instance (MI) Activity is a type of Activity that acts as a wrapper for an Activity which has multiple instances spawned in parallel or sequentially.

Operational semantics: The MI specific attributes are used to configure specific behavior. The attribute isSequential determines whether instances are generated sequentially (true) or in parallel (false). The number of instances to be generated is either specified by the integer-valued expression loopCardinality or as the cardinality of a specific collection-valued data item of the data input of the MI Activity. The latter is described in detail below.

The number of instances to be generated is evaluated once. Subsequently the number of instances are generated. If the instances are generated sequentially, a new instance is generated only after the previous has been completed. Otherwise, multiple instances to be executed in parallel are generated.

Attributes are available to support the different possibilities of behavior. The completionCondition Expression is a Boolean predicate that is evaluated every time an instance completes. When evaluated to true, the remaining instances are cancelled, a token is produced for the outgoing Sequence Flow, and the MI Activity completes.

The attribute behavior defines if and when an Event is thrown from an Activity instance that is about to complete. It has values of none, one, all, and complex, assuming the following behavior:

- **none:** an EventDefinition is thrown for all instances completing.
- **one:** an EventDefinition is thrown upon the first instance completing.
- **all:** no Event is ever thrown.
- **complex**: the complexBehaviorDefinitions are consulted to determine if and which Events to throw.

For the behaviors of none and one, an EventDefinition (which is referenced from MultipleInstanceLoopCharacteristics through the noneEvent and oneEvent associations, respectively) is thrown which automatically carries the current runtime attributes of the MI Activity. That is, the ItemDefinition of these SignalEventDefinitions is implicitly given by the specific runtime attributes of the MI Activity.

The complexBehaviorDefinition association references multiple ComplexBehaviorDefinition entities which each point to a Boolean condition being a FormalExpression and an Event which is an ImplicitThrowEvent. Whenever an Activity instance completes, the conditions of all ComplexBehaviorDefinitions are evaluated. For each ComplexBehaviorDefinition whose condition is evaluated to true, the associated Event is automatically thrown. That is, a single Activity completion may lead to multiple different Events that are thrown. The Events may then be caught on the boundary of the MI Activity. Multiple ComplexBehaviorDefinitions offer an easy way of implicitly spawning different flow at the MI Activity boundary for different situations indicating different states of progress in the course of executing the MI Activity.

The completionCondition, the condition in the ComplexBehaviorDefinition, and the DataInputAssociation of the Event in the ComplexBehaviorDefinition can refer to the MI Activity instance attributes and the loopDataInput, loopDataOutput, inputDataItem, and outputDataItem that are referenced from the MultiInstanceLoopCharacteristics.

In practice, a MI Activity is executed over a data collection, processing as input the data values in the collection and producing as output data values in a collection. The input data collection is passed to the MI outer Activity’s loopDataInput from a Data Object in the Process scope of the MI Activity. Under BPMN data flow constraints, the Data Object is linked to MI activity’s loopDataInput through a DataInputAssociation. To indicate that the Data Object is a collection, its respective symbol is marked with the MI indicator (three-bar). The items of the loopDataInput collection are used to determine the number of instances required to be executed (whether sequentially or in parallel). Accordingly, the inner instances are created and data values from the loopDataInput are extracted and assigned to the respective instances. Specifically, the values from the loopDataInput items are passed to an inputDataItem, created in the scope of the outer Activity. The value in the inputDataItem can be passed to the loopDataInput of each inner instance, where a DataInputAssociation links both. The process of extraction is left under-specified. In practice, it would entail a special-purpose mediator which not only provides the extraction and data assignment, but also any required data transformation.

Each instance processes the data value of its DataInput. It produces a value in its DataOutput if it completes successfully. The DataOutput value of the instance is passed to a corresponding outputDataItem in the outer Activity, where a DataOutputAssociation links both. Each outputDataItem value is updated in the loopDataOutput collection, in the corresponding item. The mechanism of this update is left underspecified, and again would be implemented through a special purpose mediator. The loopDataOutput is passed to the MI Activity’s Process scope through a Data Object that has a DataOutputAssociation linking both.

It should be noted that the collection in the Process scope should not be accessible until all its items have been written to. This is because, it could be accessed by an Activity running concurrently, and therefore control flow through token passing cannot guarantee that the collection is fully written before it is accessed.
The MI Activity is *compensated* only if all its *instances* have completed successfully.

**Workflow Patterns Support**: WCP-21 Structured Loop, Multiple Instance Patterns WCP 13, 14, 34, 36

### 14.3. Gateways

This section describes the behavior of Gateways.

#### 14.3.1. Parallel Gateway (Fork and Join)

![Parallel Gateway Diagram](image)

**Figure 14-3 – Merging and Branching Sequence Flow for a Parallel Gateway**

On the one hand, the **Parallel Gateway** is used to synchronize multiple concurrent branches (merging behavior). On the other hand, it is used to spawn new concurrent threads on parallel branches (branching behavior).

**Table 14-1 – Parallel Gateway Execution Semantics**

</table>
14.3.2. Exclusive Gateway (Exclusive Decision (data-based) and Exclusive Merge)

The **Exclusive Gateway** has pass-through semantics for a set of incoming branches (merging behavior). Further on, each activation leads to the activation of exactly one out of the set of outgoing branches (branching behavior).

**Figure 14-4 – Merging and Branching Sequence Flow for an Exclusive Gateway**

**Table 14-2 – Exclusive Gateway Execution Semantics**

<table>
<thead>
<tr>
<th>Operational Semantics</th>
<th>Each Token arriving at any incoming sequence flow activates the gateway and is routed to exactly one of the outgoing sequence flow.</th>

</tr>
<tr>
<td></td>
<td>the path visits a node that has a directed path to a non-empty</td>
</tr>
<tr>
<td></td>
<td>incoming sequence flow of the inclusive gateway.</td>
</tr>
</tbody>
</table>

Upon execution, a *Token* is consumed from each incoming sequence flow that has a *Token*. A *Token* will be produced on some of the outgoing sequence flows.

In order to determine the outgoing sequence flows that receive a *Token*, all conditions are evaluated. The evaluation does not have to respect a certain order.

For every condition, which evaluates to true, a *Token* must be passed on the respective sequence flow.

If and only if none of the conditions evaluates to true, the *Token* is passed on the default sequence flow.

In case all conditions evaluate to false and a default flow has not been specified, the inclusive gateway throws an exception.
**14.3.4. Event-based Gateway (Exclusive Decision (event-based))**

![Gateway Diagram](image)

The Event-Based Gateway has pass-through semantics for a set of incoming branches (merging behavior). Exactly one of the outgoing branches is activated afterwards (branching behavior), depending on which of Events of the Gateway configuration is first triggered. The choice of the branch to be taken is deferred until one of the subsequent Tasks or Events completes. The first to complete causes all other branches to be withdrawn.

When used at the Process start as a Parallel Event Gateway, only message-based triggers are allowed. The Message triggers that are part of the Gateway configuration must be part of a Conversation with the same correlation information. After the first trigger instantiates the Process, the remaining Message triggers will be a part of the Process instance that is already active (rather than creating new Process instances).

14.3.5. Complex Gateway (related to Complex Condition and Complex Merge)

![Complex Gateway Diagram]

Figure 14-7 – Merging and branching Sequence Flow for a Complex Gateway

The Complex Gateway facilitates the specification of complex synchronization behavior, in particular race situations. The diverging behavior is similar to the Inclusive Gateway. Each incoming gate of the Complex Gateway has an attribute activationCount, which can be used in an expression as an integer-valued variable. This variable represents the number of tokens that are currently on the respective incoming Sequence Flow. The Complex Gateway has an attribute activationExpression. An activationExpression is a Boolean Expression that refers to data and to the activationCount of incoming gates. For example, an activationExpression could be \(x_1+x_2+\ldots+x_m \geq 3\) stating that it needs 3 out of the \(m\) incoming gates to have a token in order to proceed. To prevent undesirable oscillation of activation of the Complex Gateway, ActivationCount variables should only be used in subexpressions of the form \(expr \geq const\) where \(expr\) is an arithmetic Expression that uses only addition and \(const\) is an Expression whose evaluation remains constant during execution of the Process.

Each outgoing Sequence Flow of the Complex Gateway has a Boolean condition that is evaluated to determine whether that Sequence Flow receives a token during the execution of the Gateway. Such a condition may refer to internal state of the Complex Gateway. There are two states: waiting for start (represented by the runtime attribute waitingForStart = true) and waiting for reset (waitingForStart=false).
### Table 14-5 – Semantics of the Complex Gateway

| Operational Semantics | The Complex Gateway is in one of the two states: *waiting for start* or *waiting for reset*, initially it is in *waiting for start*. If it is *waiting for start*, then it waits for the `activationExpression` to become *true*. The `activationExpression` is not evaluated before there is at least one *token* on some *incoming* Sequence Flow. When it becomes *true*, a *token* is consumed from each *incoming* Sequence Flow that has a *token*. To determine which *outgoing* Sequence Flow receive a *token*, all conditions on the *outgoing* Sequence Flow are evaluated (in any order). Those and only those which evaluate to *true* receive a *token*. If no condition evaluates to *true*, and only then, the *default* Sequence Flow receives a *token*. If no default flow is specified an exception is thrown. The Gateway changes its state to *waiting for reset*.

The Gateway remembers from which of the *incoming* Sequence Flow it consumed *tokens* in the first phase.

When *waiting for reset*, the Gateway waits for a *token* on each of those *incoming* Sequence Flow from which it has not yet received a *token* in the first phase unless such a *token* does not come (cf. inclusive join behavior). More precisely, the Gateway being *waiting for reset*, *resets* when for each *incoming* Sequence Flow from which no *token* was consumed in the first phase, there is either a *token* on that Sequence Flow or there is no *token* in the graph anywhere upstream of this Sequence Flow, i.e., there is no directed path (formed by Sequence Flow) from a *token* to this Sequence Flow unless

- the path visits the Complex Gateway or
- the path visits a node that has a directed path to a non-empty *incoming* Sequence Flow of the Complex Gateway or to an *incoming* Sequence Flow from which a *token* was consumed in the first phase.

When the Gateway resets, it consumes a *token* from each *incoming* Sequence Flow that has a *token* and from which it had not yet consumed a *token* in the first phase. It then evaluates all conditions on the *outgoing* Sequence Flow (in any order) to determine which Sequence Flow receives a *token*. Those and only those which evaluate to *true* receive a *token*. If no condition evaluates to *true*, and only then, the *default* Sequence Flow receives a *token*. The Gateway changes its state back to the state *waiting for start*. Note that the Gateway might not produce any *tokens* in this phase and no exception is thrown. Note that the conditions on the *outgoing* Sequence Flow may evaluate differently in the two phases, e.g., by referring to the state of the Gateway (runtime attribute *waitingForStart*). |

---
### 14.4. Events

This section describes the handling of Events.

#### 14.4.1. Start Events

For single Start Events, handling consists of starting a new Process instance each time the Event occurs. Sequence Flow leaving the Event is then followed as usual.

If the Start Event participates in a Conversation that includes other Start Events, a new Process instance is only created if none already exists for the specific Conversation (identified through its associated correlation information) of the Event occurrence.

A Process can also be started via an Event-Based Gateway. In that case, the first matching Event will create a new instance of the Process, and waiting for the other Events originating from the same decision stops, following the usual semantics of the Event-Based Exclusive Gateway. Note that this is the only scenario where a Gateway can exist without an incoming Sequence Flow.

It is possible to have multiple groups of Event-Based Gateways starting a Process, provided they participate in the same Conversation and hence share the same correlation information. In that case, one Event out of each group needs to arrive; the first one creates a new Process instance, while the subsequent ones are routed to the existing instance, which is identified through its correlation information.

#### 14.4.2. Intermediate Events

For Intermediate Events, the handling consists of waiting for the Event to occur. Waiting starts when the Intermediate Event is reached. Once the Event occurs, it is consumed. Sequence flow leaving the Event is followed as usual.

#### 14.4.3. Intermediate Boundary Events

For boundary Events, handling first consists of consuming the Event occurrence. If the cancelActivity attribute is set, the Activity the Event is attached to is then cancelled (in case of a multi-instance, all its instances are cancelled); if the attribute is not set, the Activity continues execution (only possible for Message, Signal, Timer and Conditional Events, not for Error Events). Execution then follows the Sequence Flow connected to the boundary Event.

---

**Proposal for:**
Business Process Model and Notation (BPMN), v2.0

---
14.4.4. Event Sub-Processes

Event Sub-Processes allow to handle an Event within the context of a given Sub-Processes or Process. An Event Sub-Process always begins with a Start Event, followed by Sequence Flow. Event Sub-Processes are a special kind of Sub-Process: they create a scope and are instantiated like a Sub-Process, but they are not instantiated by normal control flow but only when the associated Start Event is triggered. Event Sub-Processes are self-contained and must not be connected to the rest of the Sequence Flow in the Sub-Processes; also they cannot have attached boundary Events. They run in the context of the Sub-Process, and thus have access to its context.

An Event Sub-Process cancels execution of the enclosing Sub-Process, if the isInterrupting attribute of its Start Event is set; for a multi-instance Activity this cancels only the affected instance. If the isInterrupting attribute is not set (not possible for an Error Event Sub-Processes), execution of the enclosing Sub-Process continues in parallel to the Event Sub-Process.

An Event Sub-Process can optionally retrigger the Event through which it was triggered, to cause its continuation outside the boundary of the associated Sub-Process. In that case the Event Sub-Process is performed when the Event occurs; then control passes to the boundary Event, possibly canceling the Sub-Process (including running handlers).

Operational semantics

- A non-interrupting Event Sub-Process becomes initiated, and thus Enabled and Running, through the Activity to which it is attached. The non-interrupting Event Handler may only be initiated after the parent Activity is Running. More than one non-interrupting Event Handler may be initiated and they may be initiated at different times. There might be multiple instances of the non-interrupting Event Handler at a time.

- An Event Sub-Process completes when all tokens have reached an End Event, like any other Sub-Process. If the parent Activity enters the state Completing, it remains in that state until all contained active Event Sub-Processes have completed. While the parent Activity is in that Completing, no new Event Sub-Processes can be initiated.

14.4.5. Compensation

Compensation is concerned with undoing steps that were already successfully completed, because their results and possibly side effects are no longer desired and need to be reversed. If an Activity is still active, it cannot be compensated, but rather needs to be canceled. Cancellation in turn may result in compensation of already successfully completed portions of an active Activity, in case of a Sub-Process.

Compensation is performed by a compensation handler. A compensation handler can either be a Compensation Event Sub-Process (for a Sub-Process or Process), or an associated Compensation Activity (for any Activity). A compensation handler performs the steps necessary to reverse the effects of an Activity. In case of a Sub-Process, its Compensation Event Sub-Process has access to Sub-Process data at the time of its completion (“snapshot data”).

Compensation is triggered by a throw Compensation Event, which typically will be raised by an error handler, as part of cancellation, or recursively by another compensation handler. That Event specifies the Activity for which compensation is to be performed, either explicitly or implicitly.
**Compensation Handler**

A compensation handler is a set of Activities that are not connected to other portions of the BPMN model. The compensation handler starts with a catch Compensation Event. That catch Compensation Event either is a boundary Event, or, in case of a Compensation Event Sub-Process, the handler’s Start Event.

A compensation handler connected via a boundary Event can only perform “black-box” compensation of the original Activity. This compensation is modeled with a specialized Compensation Activity.

A Compensation Event Sub-Process is contained within a Process or a Sub-Processes. It can access data that is part of its parent, snapshot at the point in time when its parent has completed. A compensation Event Sub-Process can in particular recursively trigger compensation for Activities contained in that its parent.

It is possible to specify that a Sub-Process can be compensated without having to define the compensation handler. The Sub-Process attribute compensable, when set, specifies that default compensation is implicitly defined, which recursively compensates all successfully completed Activities within that Sub-Process, invoking them in reverse order of their forward execution.

**Compensation Triggering**

Compensation is triggered using a throw Compensation Event, which can either be an Intermediate or an End Event. The Activity which needs to be compensated is referenced. If the Activity is clear from the context, it doesn’t have to be specified and defaults to the current Activity. A typical scenario for that is an inline error handler of a Sub-Process that cannot recover the error, and as a result would trigger compensation for that Sub-Process. If no Activity is specified in a “global” context, all completed Activities in the Process are compensated.

By default, compensation is triggered synchronously, that is, the throw Compensation Event waits for the completion of the triggered compensation handler. Alternatively, compensation can just be triggered without waiting for its completion, by setting the throw Compensation Event’s waitForCompletion attribute to false.

Multiple instances typically exist for Loop or Multi-Instance Sub-Processes. Each of these has its own instance of its Compensation Event Sub-Process, which has access to the specific snapshot data that was current at the time of completion of that particular instance. Triggering compensation for the Multi-Instance Sub-Process individually triggers compensation for all instances within the current scope. If compensation is specified via a boundary compensation handler, this boundary compensation handler also is invoked once for each instance of the Multi-Instance Sub-Process in the current scope.

**Relationship between Error Handling and Compensation**

Compensation employs a “presumed abort principle”, which has a number of consequences. First, only completed Activities are compensated; compensation of a failed Activity results in an empty operation. Thus, when an Activity fails, i.e., is left because an error has been thrown, it’s the error handler’s responsibility to ensure that no further compensation will be necessary once the error handler has completed. Second, if no error Event Sub-Process is specified for a particular Sub-Process and a particular error, the default behavior is to automatically call compensation for all contained Activities of that Sub-Process if that error occurs, thus ensuring the “presumed abort” invariant.
Operational Semantics

- A Compensation Event Sub-Process becomes enabled when its parent Activity transitions into state *Completed*. At that time, a snapshot of the data associated with the parent Activity is taken and kept for later usage by the Compensation Event Sub-Process. In case the parent Activity is a *multi-instance* or *loop*, for each instance a separate data snapshot is taken, which is used when its associated Compensation Event Sub-Process is triggered.

- When *compensation* is triggered for the parent Activity, its Compensation Event Sub-Process is activated and runs. The original context data of the parent Activity is restored from the data snapshot. In case the parent Activity is a multi-instance or loop, for each instance the dedicated snapshot is restored and a dedicated Compensation Event Sub-Process is activated.

- An associated Compensation Activity becomes enabled when the Activity it is associated with transitions into state *Completed*. When *compensation* is triggered for that Activity, the associated Compensation Activity is activated. In case the Activity is a multi-instance or loop, the Compensation Activity is triggered only once, too, and thus has to compensate the effects of all instances.

- Default compensation ensures that Compensation Activities are performed in reverse order of the execution of the original Activities, allowing for concurrency when there was no dependency between the original Activities. Dependencies between original Activities that default compensation must consider are the following:
  - A Sequence Flow between Activities A and B results in compensation of B to be performed before compensation of A.
  - A data dependency between Activities A and B, e.g., through an IORules specification in B referring to data produced by A, results in compensation of B to be performed before compensation of A.
  - If A and B are two Activities that were active as part of an Ad-Hoc Sub-Process, then compensation of B must be performed before compensation of A if A completed before B started.
  - *Instances* of a loop or sequential multi-instance are compensated in reverse order of their forward completion. *Instances* of a parallel multi-instance can be compensated in parallel.
  - If a Sub-Process A has a boundary Event connected to Activity B, then compensation of B must be performed before compensation of A if that particular Event occurred. This also applies to multi-instances and loops.

14.4.6. End Events

Process level end events

For a “terminate” End Event, the Process is abnormally terminated.

For all other End Events, the behavior associated with the Event type is performed, e.g., the associated Message is sent for a Message End Event, the associated signal is sent for a Signal End Event, and so on. The Process instance is then completed, if and only if the following two conditions hold:

- All start nodes of the Process have been visited. More precisely, all Start Events have been triggered, and for all starting Event-Based Gateways, one of the associated Events has been triggered.
- There is no token remaining within the Process instance.

Sub-process level end events

For a “terminate” End Event, the Sub-Process is abnormally terminated. In case of a multi-instance Activity, only the affected instance is terminated.

For a “cancel” End Event, the Sub-Process is abnormally terminated and the associated transaction is aborted. Control leaves the Sub-Process through a cancel intermediate boundary Event.

For all other End Events, the behavior associated with the Event type is performed, e.g., the associated Message is sent for a Message End Event, the associated signal is sent for a signal End Event, and so on. The Sub-Process instance is then completed, if and only if the following two conditions hold:

- All start nodes of the Sub-Process have been visited. More precisely, all Start Events have been triggered, and for all starting Event-Based Gateways, one of the associated Events has been triggered.
- There is no token remaining within the Sub-Process instance.
15. Mapping BPMN Models to WS-BPEL

Note: The contents of this chapter is required for BPMN BPEL Process Execution Conformance or for BPMN Complete Conformance. However, this chapter is not required for BPMN Process Modeling Conformance, BPMN Process Choreography Conformance, or BPMN Process Execution Conformance. For more information about BPMN conformance types, see page 28.

This chapter covers a mapping of a BPMN model to WS-BPEL that is derived by analyzing the BPMN objects and the relationships between these objects.

A Business Process Diagram can be made up of a set of (semi-) independent components, which are shown as separate Pools, each of which represents an orchestration Process. There is not a specific mapping of the diagram itself, but rather, each of these orchestration Processes maps to an individual WS-BPEL process.

Not all BPMN orchestration Processes can be mapped to WS-BPEL in a straight-forward way. That is because BPMN allows the modeler to draw almost arbitrary graphs to model control flow, whereas in WS-BPEL, there are certain restrictions such as control-flow being either block-structured or not containing cycles. For example, an unstructured loop cannot directly be represented in WS-BPEL.

To map a BPMN orchestration Process to WS-BPEL it must be sound, that is it must contain neither a deadlock nor a lack of synchronization. A deadlock is a reachable state of the Process that contains a token on some Sequence Flow that cannot be removed in any possible future. A lack of synchronization is a reachable state of the Process where there is more than one token on some Sequence Flow. For further explanation of these terms, we refer to the literature. To define the structure of BPMN Processes, we introduce the following concepts and terminology. The Gateways and the Sequence Flow of the BPMN orchestration Process form a directed graph. A block of the diagram is a connected sub-graph that is connected to the rest of the graph only through exactly two Sequence Flow: exactly one Sequence Flow entering the block and exactly one Sequence Flow leaving the block. A block hierarchy for a Process model is a set of blocks of the Process model in which each pair of blocks is either nested or disjoint and which contains the maximal block (i.e. the whole Process model) A block that is nested in another block B is also called a subblock of B (cf. Figure 15-1).

Each block of the block hierarchy of a given BPMN orchestration Process has a certain structure (or pattern) which provides the basis for defining the BPEL mapping.
The following sections define a syntactical BPEL mapping prescribing the resulting BPEL model at the syntactical level, and a semantic BPEL mapping prescribing the resulting BPEL model in terms of its observable behavior. The syntactical BPEL mapping is defined for a subset of BPMN models based on certain patterns of BPMN blocks, whereas the semantical BPEL mapping (which extends the syntactical mapping) does not enforce block patterns, allowing for the mapping a larger class of BPMN models without prescribing the exact syntactical representation in BPEL.

### 15.1. Basic BPMN-BPEL Mapping

This section introduces a partial mapping function from BPMN orchestration Process models to WS-BPEL executable Process models by recursively defining the mapping for elementary BPMN constructs such as Tasks and Events, and for blocks following the patterns described here. Mapping a BPMN block to WS-BPEL includes mapping all of its associated attributes. The observable behavior of a WS-BPEL process resulting from a BPEL mapping is the same as that of the original BPMN orchestration Process.

We use the notation \([\text{BPMN construct}]\) to denote the WS-BPEL construct resulting from mapping the BPMN construct.

Examples are

\([\text{ServiceTask}] = \text{Invoke Activity}\)

which says that a BPMN Service Task is mapped to a WS-BPEL Invoke Activity, or
which says that the data-based exclusive choice controlled by the two predicates p1 and p2, containing the three BPMN blocks G1, G2 and G3 is mapped to the WS-BPEL on the right hand side, which recursively uses the mappings of those predicates and those sub-graphs. Note that we use the “waved rectangle” symbol throughout this section to denote BPMN blocks.

15.1.1. Process

The following figure describes the mapping of a Process, represented by its defining Collaboration, to WS-BPEL. The process itself is described by a contained graph G of flow elements) to WS-BPEL. The Process interacts with Participants Q1…Qn via Conversations C1…Cm:

The partner links of the corresponding WS-BPEL process are derived from the set of interfaces associated with each participant. Each interface of the Participant containing the Process P itself is mapped to a WS-BPEL partner link with a “myRole” specification, each interface of each other Participant Qi is mapped to a WS-BPEL partner link with a “partnerRole” specification.

The variables of the corresponding WS-BPEL process are derived from the set “{dataObjects}” of all Data Objects occurring within G, united with the set “{properties}” of all properties occurring within G, without Data Objects or properties contained in nested Sub-Processes. See Section “Handling Data” on page 467 for more details of this mapping.

The correlation sets of the corresponding WS-BPEL process are derived from the CorrelationKeys of the set of Conversations C1…Cn.. See page 451 for more details of this mapping.
15.1.2. Activities

Common Activity Mappings

The following table displays a set of mappings of general BPMN Activity attributes to WS-BPEL activity attributes.

<table>
<thead>
<tr>
<th>Activity</th>
<th>Mapping to WS-BPEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name attribute of a BPMN activity is mapped to the name attribute of a WS-BPEL activity by removing all characters not allowed in an XML NCName, and ensuring uniqueness by adding an appropriate suffix. In the subsequent diagrams, this mapping is represented as [name].</td>
</tr>
</tbody>
</table>

Task Mappings

The following sections contain the mappings of the variations of a Task to WS-BPEL.

Service Task

The following figure shows the mapping of a Service Task to WS-BPEL:

```
<invoke name="[Task-name]"
    partnerLink="[Q, Task-operation-interface]"
    portType="[Task-operation-interface]"
    operation="[Task-operation]">
    <![CDATA[...]]>
</invoke>
```

The partner link associated with the WS-BPEL invoke is derived from both the participant Q that the Service Task is connected to by Message Flow, and from the interface referenced by the operation of the Service Task.

Receive Task

The following figure shows the mapping of a Receive Task to WS-BPEL:

```
<receive name="[Task-name]"
    createInstance="[instantiate? yes\?no]"
    partnerLink="[Task-operation-interface]"
    portType="[Task-operation-interface]"
    operation="[Task-operation]">
    <![CDATA[...]]>
</receive>
```

The partner link associated with the WS-BPEL receive is derived from the interface referenced by the operation of the Receive Task.
Send Task

The following figure shows the mapping of a Send Task to WS-BPEL:

```
<![CDATA[
<invoke name="[Task-name]"
   partnerLink="[Q, Task-operation-interface]"
   portType="[Task-operation-interface]"
   operation="[Task-operation]">
   <invoke>

The partner link associated with the WS-BPEL invoke is derived from both the participant Q that the Send Task is connected to by Message Flow, and from the interface referenced by the operation of the Send Task.

Abstract Task

The following figure shows the mapping of an Abstract Task to WS-BPEL:

```
<![CDATA[
<empty name="[Task-name]">
</empty>
```

Service Package

Message

For Messages with a scalar data item definition typed by an XML schema definition, the following figure shows the mapping to WS-BPEL, using WSDL 1.1:

```
<![CDATA[
<Message name="msg-name">
   <StructureDefinition typeLanguage="xmlSchema" href="http://www.w3.org/2001/XMLSchema">
      <xmlSchema>
         <StructureDefinition>
      </xmlSchema>
   </StructureDefinition>
</Message>
```

The top-level child elements of the XML schema defining the structure of the BPMN Message are mapped to the WSDL’s message’s parts.
Interface and Operation

The following figure shows the mapping of a BPMN interface with its operations to WS-BPEL, using WSDL 1.1:

Conversations and Correlation

For those BPMN nodes sending or receiving Messages (i.e., Message Events, Service, send or Receive Tasks) that have an associated key-based Correlation Key, the mapping of that key-based Correlation Key is as follows:

The messageType of the BPEL property alias is appropriately derived from the itemDefinition of the Message referenced by the BPMN Message key expression. The name of the Message part is derived from the Message key expression. The Message key expression itself is transformed into an expression relative to that part.

The mapping of Activities with an associated key-based Correlation Key is extended to reference the above BPEL correlation set in the corresponding BPEL correlations element. The following figure shows that mapping in the case of a Service Task with an associated key-based Correlation Key:

Proposal for:
Business Process Model and Notation (BPMN), v2.0 452
The initiate attribute of the BPEL correlation element is set depending on whether or not the associated Message Flow initiates the associated Conversations, or participates in an already existing Conversation. If there are multiple CorrelationKeys associated with the Conversation, multiple correlation elements are used.

**Sub-Process Mappings**

The following table displays the mapping of an embedded Sub-Process with Adhoc="False" to a WS-BPEL scope. (This extends the mappings that are defined for all Activities--see page 450):

The following figure shows the mapping of a BPMN Sub-Process without an Event Sub-Process:

The following figure shows the mapping of a BPMN Sub-Process with an Event Sub-Process. (Event Sub-Processes could also be added to a top-level Process, in which case their mapping extends correspondingly.)

Note that in case of multiple Event Sub-Processes, there would be multiple WS-BPEL handlers.

**Mapping of Event Sub-Processes**

Note that if a Sub-Process contains multiple Event Sub-Processes, all become handlers of the associated WS-BPEL scope, ordered and grouped as specified by WS-BPEL.

Non-interrupting Message Event Sub-Processes are mapped to WS-BPEL event handlers as follows:
Timer Event Sub-Processes are mapped to WS-BPEL event handlers as follows:

\[ \text{Timer Event Sub-Processes} \]

Error Event Sub-Processes are mapped to WS-BPEL fault handlers as follows:

\[ \text{Error Event Sub-Processes} \]

A Compensation Event Sub-Process is mapped to a WS-BPEL compensation handler as follows:

\[ \text{A Compensation Event Sub-Process} \]

Activity Loop Mapping

Standard loops with a testTime attribute “Before” or “After” execution of the Activity map to WS-BPEL while and repeatUntil activities in a straight-forward manner. When the LoopMaximum attribute is used, additional activities are used to maintain a loop counter.

Multi-instance Activities map to WS-BPEL forEach activities in a straight-forward manner.

Standard Loops

The mappings for standard loops to WS-BPEL are described in the following.

A standard loop with testTime= “Before” maps to WS-BPEL as follows, where \( p \) denotes the loop condition:
A standard loop with testTime= “After” maps as follows, where $p$ denotes the loop condition:

\[
\begin{array}{c}
\text{Task} \\
\hline
\end{array}
= \begin{array}{c}
\text{<repeatUntil>}
\text{[Task]}
\text{<condition>}[not p]\text{</condition>}
\text{</repeatUntil>}
\end{array}
\]

Dealing with LoopMaximum

When the LoopMaximum attribute is specified for an Activity, the loop requires additional set up for maintaining a counter.

A standard loop with testTime=“Before” and a LoopMaximum attribute maps to WS-BPEL as follows (again, $p$ denotes the loopCondition):

\[
\begin{array}{c}
\text{Task} \\
\hline
\end{array}
= \begin{array}{c}
\text{<variable name="$counter" type="xsd:integer"/>}
\text{...}
\text{<sequence>}
\text{<assign>}
\text{<copy>}
\text{<from>$\text{l}0$</from>}
\text{<to variable="$counter$"/>}
\text{</copy>}
\text{</assign>}
\text{<while>}
\text{<condition>}[p] \text{and $\text{counter$} &lt; \text{[LoopMaximum]}\text{</condition>}
\text{<sequence>}
\text{[G]}
\text{<assign>}
\text{<copy>}
\text{<from expression="$\text{counter}+1$"/>}
\text{<to variable="$counter$"/>}
\text{</copy>}
\text{</assign>}
\text{</sequence>}
\text{</while>}
\text{</sequence>}
\end{array}
\]

(The notation [$counter$] denotes the unique name of a variable used to hold the counter value; the actual name is immaterial.)

A standard loop with testTime=“After” and a LoopMaximum attribute maps as follows:
Multi-Instance Activities

A BPMN Multi-Instance Task with a multiInstanceFlowCondition of “All” is mapped to WS-BPEL as follows:

(The notation \([\text{counter}]\) denotes the unique name of a variable used to hold the counter value; the actual name is immaterial.)

15.1.3. Events

Start Event Mappings

The following sections detail the mapping of Start Events to WS-BPEL.
Message Start Events

A Message Start Event is mapped to WS-BPEL as shown in the following figure:

```
<receive name="[e-name]"
  createInstance="yes"
  partnerLink="[e-operation-interface]"
  portType="[e-operation-interface]"
  operation="[e-operation]">
  ...
</receive>
```

The partner link associated with the WS-BPEL receive is derived from the interface referenced by the operation of the Message Start Event.

Error Start Events

An Error Start Event can only occur in Event Sub-Processes. This mapping is described on page 453.

Compensation Start Events

A Compensation Start Event can only occur in Event Sub-Processes. This mapping is described on page 453.

Intermediate Event Mappings (Non-boundary)

The following sections detail the mapping of intermediate non-boundary Events to WS-BPEL.

Message Intermediate Events (Non-boundary)

A Message Intermediate Event can either be used in normal control flow, similar to a Send or Receive Task (for throw or catch Message Intermediate Events, respectively), or it can be used in an Event Gateway. The latter is described in more detail in Section 5.1.4.

The following figure describes the mapping of Message Intermediate Events to WS-BPEL:

```
<receive name="[e-name]"
  createInstance="no"
  partnerLink="[e-operation-interface]"
  portType="[e-operation-interface]"
  operation="[e-operation]">
  ...
</receive>
```

The partner link associated with the WS-BPEL receive is derived from the interface referenced by the operation of the Message Intermediate Event.

Timer Intermediate Events (Non-boundary)

A Timer Intermediate Event can either be used in normal control flow, or it can be used in an Event Gateway. The latter is described in more detail in Section 15.1.4.
The following figure describes the mapping of a Timer Intermediate Event to WS-BPEL – note that one of the mappings shown is chosen depending on whether the Timer Event’s TimeCycle or TimeDate attribute is used:

\[
\text{<wait name="[e-name]" for="[e-TimeCycle]"/> or \text{<wait name="[e-name]" until="[e-TimeDate]"/>}}
\]

Compensation Intermediate Events (Non-boundary)

A Compensation Intermediate Event with its waitForCompletion property set to true, that is used within an Event Sub-Process triggered through an error or through compensation, is mapped to WS-BPEL as follows:

\[
\text{<compensate/> or \text{<compensateScope target="[referencedActivity]"/>}}
\]

The first mapping is used if the Compensation Event does not reference an Activity, the second mapping is used otherwise.

**End Event Mappings**

The following sections detail the mapping of End Events to WS-BPEL.

**None End Events**

A “none” End Event marking the end of a Process is mapped to WS-BPEL as shown in the following figure:

\[
\text{<empty name="[e-name]">}\text{</empty>}
\]

**Message End Events**

A Message Start Event is mapped to WS-BPEL as shown in the following figure:
The partner link associated with the WS-BPEL invoke is derived from both the participant Q that the Message Intermediate Event is connected to by Message Flow, and from the interface referenced by the operation of the Message Intermediate Event.

Error End Events

An Error End Event is mapped to WS-BPEL as shown in the following figure:

```
  e
```

```
  <throw faultName="[e-name]">
  </throw>
```

Compensation End Events

A Compensation End Event with its waitForCompletion property set to true, that is used within an Event Sub-Process triggered through an error or through compensation, is mapped to WS-BPEL as follows:

```
  e
```

```
  <compensate/>
  or
  <compensateScope target="[referencedActivity]"/>
```

The first mapping is used if the Compensation Event does not reference an Activity, the second mapping is used otherwise.

Terminate End Events

A Terminate End Event is mapped to WS-BPEL as shown in the following figure:

```
  e
```

```
  <exit>
  </exit>
```
Boundary Intermediate Events

Message Boundary Events

A BPMN Activity with a non-interrupting Message boundary Event is mapped to a WS-BPEL scope with an event handler as follows:

The partner link associated with the WS-BPEL onEvent is derived from the interface referenced by the operation of the boundary Message Event.

The same mapping applies to a non-interrupting boundary Timer Event, using a WS-BPEL onAlarm handler instead.

Error Boundary Events

A BPMN Activity with a boundary Error Event according to the following pattern is mapped as shown:
Note that the case where the error handling path doesn’t join the main control flow again, is still mapped using this pattern, by applying the following model equivalence:

Compensation Boundary Events

A BPMN Activity with a boundary Compensation Event is similarly mapped as shown:
Multiple Boundary Events, and Boundary Events with Loops

If there are multiple boundary Events for an Activity, their WS-BPEL mappings are super-imposed on the single WS-BPEL scope wrapping the mapping of the Activity.

When the Activity is a standard loop or a multi-instance and has one or more boundary Events, the WS-BPEL loop resulting from mapping the BPMN loop is nested inside the WS-BPEL scope resulting from mapping the BPMN boundary Events.

The following example shows that mapping for a Sub-Process with a nested Event Sub-Process that has a standard loop with TestTime="Before", an boundary Error Intermediate Event, and a boundary Compensation Intermediate Event.
15.1.4. Gateways and Sequence Flow

The mapping of BPMN Gateways and Sequence Flow is described using BPMN blocks following particular patterns.

**Exclusive (Data-based) Decision Pattern**

An exclusive data-based decision is mapped as follows:
While this figure shows three branches, the pattern is generalized to $n$ branches in an obvious manner.

**Exclusive (Event-based) Decision Pattern**

An Event Gateway is mapped as follows:

While this figure shows three branches with one Message Intermediate Event, one Receive Task and one Timer Intermediate Event, the pattern is generalized to $n$ branches with any combination of the former in an obvious manner. The handling of Participants (BPEL partnerLinks), Event (operation) and timer details is as specified for Message Intermediate Events, Receive Tasks and Timer Intermediate Events, respectively. The data flow and associated variables (not shown) are handled as for Receive Tasks/Message Intermediate Events.

**Inclusive Decision Pattern**

An inclusive decision pattern without an otherwise gate is mapped as follows:
While this figure shows three branches, the pattern is generalized to $n$ branches in an obvious manner.

Note that link names in WS-BPEL must follow the rules of an XML NCName. Thus, the mapping of the BPMN Sequence Flow name attribute must appropriately canonicalize that name, possibly ensuring uniqueness, e.g., by appending a unique suffix. This is capture by the [linkName] notation.
**Parallel Pattern**

A parallel fork-join pattern is mapped as follows:

```
<flow>
  [G1]
  [G2]
  [G3]
</flow>
```

**Sequence Pattern**

A BPMN block consisting of a series of Activities connected via (unconditional) Sequence Flow is mapped to a WS-BPEL sequence:

```
<sequence>
  [G1]
  [G2]
  [G3]
</sequence>
```

**Structured Loop Patterns**

A BPMN block consisting of a structured loop of the following pattern is mapped to a WS-BPEL while:

```
<while>
  <condition>[p]</condition>
  [G]
</while>
```

A BPMN block consisting of a structured loop of the following pattern is mapped to a WS-BPEL repeat Until:
Handling Loops in Sequence Flow

Loops are created when the flow of the Process moves from a downstream object to an upstream object. There are two types of loops that are WS-BPEL mappable: while loops and repeat loops.

A while loop has the following structure in BPMN and is mapped as shown:

A repeat loop has the following structure in BPMN and is mapped as shown:

15.1.5. Handling Data

Data Objects

BPMN Data Objects are mapped to WS-BPEL variables. The itemDefinition of the Data Object determines the XSD type of that variable.

Data Objects occur in the context of a Process or Sub-Process. For the associated WS-BPEL process or WS-BPEL scope, a variable is added for each Data Object in the corresponding WS-BPEL variables section, as follows:
Properties

BPMN properties can be contained in a Process, Activity or an Event, here named the “container” of the property. A BPMN property is mapped to a WS-BPEL variable. Its name is derived from the name of its container and the name of the property. Note that in the case of different containers with the same name and a contained property of the same name, the mapping to WS-BPEL ensures the names of the associated WS-BPEL variables are unique. The itemDefinition of the property determines the XSD type of that variable.

A BPMN Process property is mapped to a WS-BPEL global variable. A BPMN Event property is mapped to a WS-BPEL variable contained in the WS-BPEL scope representing the immediately enclosing Sub-Process of the Event (or a global variable in case the Event is an immediate child of the Process). For a BPMN Activity property, two cases are distinguished: In case of a Sub-Process, the WS-BPEL variable is contained in the WS-BPEL scope representing the Sub-Process. For all other BPMN Activity properties, the WS-BPEL variable is contained in the WS-BPEL scope representing the immediately enclosing Sub-Process of the Activity (or a global variable in case the Activity is an immediate child of the Process).

Input and Output Sets

For a Send Task and a Service Task, the single input set is mapped to a WSDL message defining the input of the associated WS-BPEL activity. The inputs map to the message parts of the WSDL message. For a Receive Task and a Service Task, the single output set is mapped to a WSDL message defining the output of the associated WS-BPEL activity. The outputs map to the message parts of the WSDL message.

The structure of the WSDL message is defined by the itemDefinitions of the data inputs of the input set:

For the data outputs of the output set, the WSDL message looks as follows:
Data Associations

In this section, we assume that the input set of the Service Task has the same structure as its referenced input Message, and the output set of the Service Task has the same structure as its reference output Message. If this is not the case, assignments are needed, and the mapping is as described in the next section.

Data associations to and from a Service Task are mapped as follows:

Data associations from a Receive Task are mapped as follows:

Data associations to a Send Task are mapped as follows:

Expressions

BPMN expressions specified using XPath (e.g., a condition expression of a Sequence Flow, or a timer cycle expression of a Timer Intermediate Event) are used as specified in BPMN, rewriting access to BPMN context to refer to the mapped BPEL context.
The BPMN XPath functions for accessing context from the perspective of the current Process are mapped to BPEL XPath functions for context access as shown in the following table. This is possible because the arguments must be literal strings.

Table 15-2 – Expressions mapping to WS-BPEL

<table>
<thead>
<tr>
<th>BPMN context access</th>
<th>BPEL context access</th>
</tr>
</thead>
<tbody>
<tr>
<td>getDataobject(dataObjectName)</td>
<td>${dataObjectName}</td>
</tr>
<tr>
<td>getProcessProperty(propertyName)</td>
<td>${[processName}.propertyName] where the right processName is statistically derived.</td>
</tr>
<tr>
<td>getActivityProperty(activityName, propertyName)</td>
<td>${activityName.propertyName}</td>
</tr>
<tr>
<td>getEventProperty(eventName, propertyName)</td>
<td>${eventName.propertyName}</td>
</tr>
</tbody>
</table>

**Assignments**

For a Service Tasks with assignments, the WS-BPEL mapping results in a sequence of an assign activity, an invoke activity and another assign activity. The first assign deals with creating the service request Message from the data inputs of the Task, the second assign deals with creating the data outputs of the Task from the service response Message.

### 15.2. Extended BPMN-BPEL Mapping

Additional sound BPMN Process models whose block hierarchy contains blocks that have not been addressed in the previous section can be mapped to WS-BPEL. For such BPMN Process models, in many cases there is no preferred single mapping of a particular block, but rather, multiple WS-BPEL patterns are possible to map that block to. Also, additional BPMN constructs can be mapped by using capabilities not available at the time of producing this specification, such as the upcoming OASIS BPEL4People standard to map BPMN User Tasks, or other WS-BPEL extensions.

Rather than describing or even mandating the mapping of such BPMN blocks, this specification allows for a semantic mapping of a BPMN Process model to an executable WS-BPEL process: The observable behavior of the target WS-BPEL process MUST match the operational semantics of the mapped BPMN Process. Also, the mappings described in Section 5.1 SHOULD be used where applicable.

### 15.2.1. End Events

End Events can be combined with other BPMN objects to complete the merging or joining of the paths of a WSBPEL structured element (see Figure 7-3).
15.2.2. Loop/Switch Combinations From a Gateway

This type of loop is created by a Gateway that has three or more outgoing Sequence Flow. One Sequence Flow loops back upstream while the others continue downstream (see Figure 15-3). Note that there might be intervening Activities prior to when the Sequence Flow loops back upstream.

- This maps to both a WSBPEL while and a switch. Both activities will be placed within a sequence, with the while preceding the switch.
- For the while:
  - The Condition for the Sequence Flow that loops back upstream will map to the condition of the while.
  - All the Activities that span the distance between where the loop starts and where it ends, will be mapped and placed within the Activity for the while, usually within a sequence.
- For the switch:
  - For each additional outgoing Sequence Flow there will be a case for the switch.
15.2.3. Interleaved Loops

This is a situation where there at least two loops involved and they are not nested (see Figure 15-4). Multiple looping situations can map, as described above, if they are in a sequence or are fully nested (e.g., one while inside another while). However, if the loops overlap in a non-nested fashion, as shown in Figure, then the structured element while cannot be used to handle the situation. Also, since a flow is acyclic, it cannot handle the behavior either.
Figure 15-4 – An example of interleaved loops

To handle this type of behavior, parts of the WSBPEL process will have to be separated into one or more derived processes that are spawned from the main process and will also spawn or call each other (note that the examples below are using a spawning technique). Through this mechanism, the linear and structured elements of WSBPEL can provide the same behavior that is shown through a set of cycles in a single BPMN diagram. To do this:

- The looping section of the Process, where the loops first merge back (upstream) into the flow until all the paths have merged back to Normal Flow, shall be separated from the main WSBPEL process into a set of derived processes that will spawn each other until all the looping conditions are satisfied.

- The section of the process that is removed will be replaced by a (one-way) invoke to spawn the derived process, followed by a receive to accept the message that the looping sections have completed and the main process can continue (see Figure 15-5).

- The name of the invoke will be in the form of:
  - “Spawn_{(loop target)activity.Name}_Derived_Process”
  - The name of the receive will be in the form of:
  - “{((loop target)activity.Name)}_Derived_Process_Completed”
For each location in the Process where a Sequence Flow connects upstream, there will be a separate derived WSBPEL process.

- The name of the derived process will be in the form of:
  - "[(loop target)activity.Name]_Derived_Process"
- All Gateways in this section will be mapped to switch elements, instead of while elements (see Figure below).
- Each time there is a Sequence Flow that loops back upstream, the Activity for the switch case will be a (one-way) invoke that will spawn the appropriate derived process, even if the invoke spawns the same process again.
- The name of the invoke will the same as the one describe above.
- At the end of the derived process a (one-way) invoke will be used to signal the main process that all the derived activities have completed and the main process can continue.
- The name of the invoke will be in the form of:
  - "[(loop target)activity.Name]_Derived_Process_Completed"
15.2.4. Infinite Loops

This type of loop is created by a Sequence Flow that loops back without an intervening Gateway to create alternative paths (see Figure 15-7). While this may be a modeling error most of the time, there may be situations where this type of loop is desired, especially if it is placed within a larger Activity that will eventually be interrupted.

- This will map to a while activity.
- The condition of the while will be set to an expression that will never evaluate to true, such as condition "1 = 0."
- All the activities that span the distance between where the loop starts and where it ends, will be mapped and placed within the activity for the while, usually within a sequence.

Figure 15-7 – An example – An infinite loop

15.2.5. BPMN Elements that Span Multiple WSBPEL Sub-Elements

Figure 15-8 below illustrates how BPMN objects may exist in two separate sub-elements of a WSBPEL structured element at the same time. Since BPMN allows free form connections of Activities and Sequence Flow, it is possible that two (or more) Sequence Flow will merge before all the Sequence Flow that map to a WSBPEL structure element have merged. The sub-elements of a WSBPEL structured elements are also self-contained and there is no cross sub-element flow. For example, the cases of a switch cannot interact; that is, they cannot share activities. Thus, one BPMN Activity will need to appear in two (or more) WSBPEL structured elements. There are two possible mechanisms to deal with the situation:

- First, the activities are simply duplicated in all appropriate WSBPEL elements.
- Second, the activities that need to be duplicated can be removed from the main Process and placed in a derived process that is called (invoked) from all locations in the WSBPEL elements as required.
  - The name of the derived process will be in the form of:
    - "[target]object.Name_Derived_Process"
Figure 15-8 below displays this issue with an example. In that example, two Sequence Flow merge into the “Include History of Transactions” Task. However, the Decision that precedes the Task has three (3) alternatives. Thus, the Decision maps to a WSBPEL switch with three (3) cases. The three cases are not closed until the “Include Standard Text” Task, downstream. This means that the “Include History of Transactions” Task will actually appear in two (2) of the three (3) cases of the switch.

Note – the use of a WSBPEL flow will be able to handle the behavior without duplicating activities, but a flow will not always be available for use in these situations, particularly if a WSBPEL pick is required.

Figure 15-8 – An example – Activity that spans two paths of a WSBPEL structured element
16. Exchange Formats

16.1. Interchanging Incomplete Models

In practice, it is common for models to be interchanged before they are complete. This occurs frequently when doing iterative modeling, where one user (such as a subject matter expert or business person) first defines a high-level model, and then passes it on to another user to be completed and refined.

Such "incomplete" models are ones in which all of the required attributes have not yet been filled in, or the cardinality lowerbound of attributes and associations has not been satisfied.

XMI allows for the interchange of such incomplete models. In BPMN, we extend this capability to interchange of XML files based on the BPMN XSD. In such XML files, implementers are expected to support this interchange by:

- Disregarding missing attributes that are marked as 'required' in the XSD.
- Reducing the lower bound of elements with 'minOccurs' greater than 0.

16.2. XSD

The BPMN 2.0 XSD for the interchange of semantic information can be found in OMG Document bmi/2009-05-05

The BPMN 2.0 XSD for the interchange of diagram information can be found in OMG Document bmi/2009-05-06

References within the BPMN XSD

All BPMN elements contain IDs and within the BPMN XSD, references to elements are expressed via these IDs. The XSD IDREF type is the traditional mechanism for referencing by IDs, however it can only reference an element within the same file. The BPMN XSD supports referencing by ID, across files, by utilizing QNames. A QName consists of two parts: an optional namespace prefix and a local part. When used to reference a BPMN element, the local part is expected to be the ID of the element.

For example, consider the following Process

```xml
<process name="Patient Handling" id="Patient_Handling_Process_ID1"> ... </process>
```

When this Process is referenced from another file, the reference would take the following form:

```xml
processRef="process_ns:Patient_Handling_Process_ID1"
```

where "process_ns" is the namespace prefix associated with the process namespace upon import, and "Patient_Handling_Process_ID1" is the value of the id attribute for the Process.

The BPMN XSD utilizes IDREFs wherever possible and resorts to QName only when references may span files. In both situations however, the reference is still based on IDs.
16.3. XMI

The BPMN 2.0 XMI for the interchange of semantic information can be found in OMG Document bmi/2009-05-04

The BPMN 2.0 XMI for the interchange of diagram information can be found in OMG Document bmi/2009-05-06

16.4. XSLT Transformation between XSD and XMI

The BPMN 2.0 XSLT for the transformation between XSD and XMI can be found in OMG Document bmi/2009-05-07

Changes from BPMN V1.2

There have been notational and technical changes to the BPMN specification.

The major notational changes include:

- The addition of a Choreography diagram
- The addition of a Conversation diagram
- Non-interrupting Events for a Process
- Event Sub-Processes for a Process

The major technical changes include:

- A formal metamodel as shown through the class diagram figures
- Interchange formats for semantic model interchange in both XMI and XSD
- Interchange formats for diagram interchange in both XMI and XSD
- XSLT transformations between the XMI and XSD formats
Annex B

(Non-Normative)

Diagram Interchange

This non-normative appendix explains the mechanism that was used to create BPMN 2.0's normative diagram interchange specification. The mechanism is a generic approach to diagram interchange that can be applied to multiple languages, and that in this particular case was applied to BPMN 2.0. The mechanism has been submitted as a response to the OMG's Diagram Definition RFP. It is the intention of the BPMN 2.0 submitters that the BPMN 2.0 FTF will adjust BPMN 2.0's normative diagram interchange specification to align it with the outcome of the OMG's Diagram Definition specification process, and it is our intention that at that time the FTF will remove this appendix from the BPMN 2.0 specification.

Overview

The goal of the Diagram Interchange (DI) metamodel is to provide a way for BPMN to persist and interchange diagrams. Having common interchange format benefits tool interoperability, which is an ever increasing demand by end users. The DI metamodel, similar to the BPMN semantic metamodel, is defined as a MOF-based metamodel and hence its instances are serialized and interchanged with XMI.

Furthermore, a lot of the design decisions that characterize DI are motivated and influenced by experiences gained by working with similar technologies in the industry. Some of the major concerns in the industry for the adoption of any specification, but more critically for such a core one as DI, is its complexity, maintainability and scalability.

With regards to complexity concern, there are two major principles driving the design of DI. The first one is having a simple yet solid core, while allowing for variability using extensions. Obviously, there is no single diagram definition that suits the requirements of all possible domains and tools. However, it is certainly possible to define a minimal core that captures the main design pattern and make it extensible to address more specific requirements. Some typical extension mechanisms for metamodels include inheritance and redefinition. However, if not done very carefully (which is often the case), these extensions can easily lead to non-conforming extensions creeping in that would hurt the interchange and break the potential generality of diagramming tools. In addition, this would cause every domain or tool to have its own extended diagram metamodel and consequently XMI schema hindering reuse and interchange. For those reasons, the DI metamodel is kept closed for extension by inheritance. Instead, the metamodel focuses on defining a core design pattern for diagram persistence that is minimally constrained and allows for adding domain or tool specific extensions and/or constraints by referencing instances of another language called Diagram Definition (discussed in Chapter 13, as shown in Figure 16-1).

The second principle of managing complexity is the separation between the business data and its diagram data, or more idiomatically between the model and its view. The business data of BPMN is represented by its abstract syntax metamodel, where the diagram data needs to be captured in a separate metamodel (DI) that references the former as its context, as shown in Figure 16-1. There are several advantages to this design including: the ability

---

4 The normative BPMN 2.0 diagram interchange specification has two parts. One part is Chapter 13 of this document. The other part is OMG document <omg document #>, which contains the diagram interchange schema
of both metamodels to evolve independently, the ability of BPMN elements to have multiple alternate notations, the ability of a BPMN element to be depicted more than once using the same notation and the ability of a notation to be defined using multiple diagram elements. This flexibility leads to more efficient and less bloated metamodel design for BPMN’s diagram interchange.

![Diagram](image.png)

**Figure 16-1 – The relationship between DI, DD and a BPMN’s abstract-syntax metamodels**

Regarding the maintainability concern, the fact that the DI metamodel is small and closed coupled with the built in separation of concern between the diagram interchange and its definition imply that the diagram interchange schema is less susceptible to change. This allows, for example, small extensions to be done to the diagram definition without affecting the diagram interchange, which can dramatically reduce the maintenance cost for tools. It also allows several unrelated extensions to be made without affecting their ability to coexist again reducing maintenance costs.

As for the scalability concern, the metamodel design focuses on eliminating redundancy as well as opting for alternatives that have more potential to scale better in realistic user setting. The scalability dimensions of importance here are memory footprint and change deltas. The details of the metamodel are given in the remainder of this chapter and wherever alternatives exist, a justification for the chosen alternative is given.

**Metamodel Description**

The underlying pattern of the DI metamodel is based on graph theory. The basic abstraction in DI is called a View, which describes an attributed graph element. A view owns a collection of name/value pairs representing its appearance attributes or styles. A View is further specialized into several kinds that correspond to the different components of a graph. One kind of view is Diagram, corresponding to the graph itself, which is the containment root for all other views in the diagram. The other kinds are Node and Connector. A Node corresponds to a graph node and represents a child view that is contained by another view. A Connector corresponds to a graph connector and represents a relationship between two views (a source and a target). DI’s view hierarchy is shown in Figure 16-2.
As mentioned in the previous section, the DI metamodel is related to the abstract syntax metamodel and to the DD metamodel. The relationship to the abstract syntax metamodel is manifested in the view having an optional reference to MOF-based context object (which could be BPMN elements or others). When a view has a reference to a context object it is said to “visualize” this object. The relationship to the DD metamodel is manifested in the view having references to one or more view definitions. A view definition classifies a view, defines its proper form and specifies rules for its validation. These rules include definitions for the type of context object, the allowed styles and the allowed children of the view, in addition to arbitrary constraints. The first definition is the main definition that characterizes the view. The other optional definitions can be added by domain extensions and/or tool implementations to extend the definition of the view.

Class Description

View

A view is the main abstraction in the DI metamodel. It is also the building block of a diagram. It represents a unit of diagrammatic notation. A view may be purely notational, in which case it conveys information that is not in any other model. A view may also represent, by itself or with other views, the graphical notation of a context object from a MOF-based abstract syntax model (like BPMN models). View is an abstract metaclass that is further sub classed into three concrete kinds: Diagram, Node and Connector.

In addition to referencing a context object, a view contains a collection of styles (name/value pairs) representing its appearance properties (e.g. colors, line attributes, layout constraints...etc). It also contains a collection of nested child views, which add to its notation. A view also has two collections of references to source and target connectors. All these features give a view the flexibility to meet the syntactical requirement of a large set of domains, while still conforming to a common design pattern.

However, for a particular view instance, there must be a definition of its expected valid syntax. That is why a view references one or more view definitions that classify the view and specify its valid syntax. The first
A view’s context object has to conform to the context type specified by all its view definitions together.

Each style owned by a view has to correspond to exactly one style definition contained by one of the view’s definitions. The correspondence is achieved when the name of a style matches the name of a style definition. Also the value of a style has to conform to the primitive type specified in its style definition.

Each nested child view has to correspond to exactly one child definition contained by one of the view’s definitions. The correspondence is achieved when the role of a child matches the name of a child definition. The number of child views playing this role has to be compatible with the multiplicity specified by that child definition.

All constraints contained by all view definitions referenced by a view have to be satisfied together on the view.

Furthermore, with regard to styles, DI specifies that a style can either be specified directly on the view or inherited from a parent view (if the style is defined as inherited in one of the style definitions owned by the view’s definitions). Therefore, the style value is calculated as follows:

- the view’s owned style value
- otherwise, the parent view’s style value (if the view has a parent and the style is inherited)
- otherwise, the style’s default value from the style definition
- otherwise, the style’s type’s natural default value

### Properties

</tr>
<tr>
<td>styles: Style [0..*]</td>
<td>Contains a collection of styles (name/value pairs) providing override values for the view’s appearance properties.</td>
</tr>
</tbody>
</table>

Constraints

- A view cannot have more than one style instance with the same name.
- A view has to conform to all its view definitions

Operations

- The query getDiagram() returns the view’s diagram by walking the view’s containment chain up to a diagram
- The query getStyleValue(name: String) gets the value of the style with the given name by applying the style calculation algorithm given above.

Diagram

A diagram is a special kind of view that has a name and designates the root of containment for all views in one diagram. A diagram directly contains all top level nodes, through the inherited ‘child’ association. It also directly contains all connectors in the same diagram regardless of the nesting level of their source and target views. This simplifies connector containment as it does not need to change in response to reconnections to different sources or targets.

Generalizations

- View

Properties

**Table 16-5 – Diagram attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: String</td>
<td>The name of the diagram</td>
</tr>
<tr>
<td>connector: Connector [0..*]</td>
<td>Contains a list of connectors in the diagram. Each connector’s source and target views have to be nested in the same diagram.</td>
</tr>
</tbody>
</table>

Constraints

- A diagram can only be defined by DiagramDefinitions.
**Node**

A node is a special kind of view that can be nested (playing a child role) in some other view. It also represents a bounded area in the diagram that can be laid out (positioned and/or sized). The order of a node in its parent’s child collection may or may not have an impact of how the node gets laid out. Nodes can represent notational idioms or play notational roles that are described in various graphical specifications. For example, they can represent “shapes” on diagrams, “compartments” on shapes, “labels” on connectors...etc.

**Generalizations**
- View

**Properties**

*Table 16-6 – Node attributes and model associations*

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>role: String</td>
<td>The role played by this node as a child in its parent.</td>
</tr>
<tr>
<td>parent: View</td>
<td>References the node’s parent view that contains this node.</td>
</tr>
</tbody>
</table>

**Constraints**
- A node can only be defined by NodeDefinitions.
- The node’s role must correspond to the name of exactly one of the child definitions contained by the view definitions defining the node’s parent view.

**Connector**

A connector is a kind of view that connects two other views: a source view and a target view. A connector is rendered as a line going from the source to the target view. The line may be divided into segments by specifying bend points along its route. Bend points constrain the routing by forcing the connector’s line to pass through them. A connector may own a collection of label nodes, through its inherited ‘child’ property. Labels are laid out relative to connector’s line.

**Generalizations**
- View

**Properties**

*Table 16-7 – Connector attributes and model associations*

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>

<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**bendpoint**: Bendpoint \([0..\ast]\)  
Contains a list of bendpoints for the connector. Each bendpoint specify an offset from the connector’s source and target anchoring points.

<table>
<thead>
<tr>
<th><strong>source</strong>: View</th>
<th>References the connector’s source view.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>target</strong>: View</td>
<td>References the connector’s source view.</td>
</tr>
<tr>
<td><strong>diagram</strong>: Diagram</td>
<td>References the connector’s diagram that owns the connector.</td>
</tr>
</tbody>
</table>

**Constraints**
- A connector can only be defined by ConnectorDefinitions.
- The connector’s source view has to be nested in the same diagram as the connector.
- The connector’s target view has to be nested in the same diagram as the connector.
- A connector cannot reference itself as a source or a target view.

**Bendpoint**

A bend point is a data type, which represents a point that a connector has to pass through in its route. A bend point is described by 2 offsets from the connector’s source and target anchor points, as shown in Figure 16-3. Describing a bendpoint this way preserves its relative position when the connector’s source and/or target change bounds.

<tr>
<td>sourceY: Integer</td>
<td>The bendpoint’s offset from the source anchor along the y-axis.</td>
</tr>
<tr>
<td>targetX: Integer</td>
<td>The bendpoint’s offset from the target anchor along the x-axis.</td>
</tr>
<tr>
<td>targetY: Integer</td>
<td>The bendpoint’s offset from the target anchor along the y-axis.</td>
</tr>
</tbody>
</table>

Style

A style is a data type consisting of a string name/value pair. It represents an appearance property for a view such as colors, line styles, layout constraints, drawing options...etc. The set of possible styles for a given view is given by the view’s definition. Each style is defined by its name, type and default value. Instances of the style datatype represent a particular instance of a style with a given value.

Although the style’s type may be an arbitrary data type, the style’s value is always encoded as a string. For example if the style’s type is a Boolean, the possible values would be the string literal “true” or “false”.

Properties

Table 16-9 – Style attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: String</td>
<td>The style’s name string.</td>
</tr>
<tr>
<td>value: String</td>
<td>The style’s value encoded as a string.</td>
</tr>
</tbody>
</table>

Constraints

- The style’s string value is compatible with the style’s defined type.
Diagram Definition

Overview

The previous chapter presented DI, a metamodel to create and persist diagrams. DI defines a schema for diagrams that is both flexible and domain independent. However, in order to interchange diagrams between domain specific tools, like BPMN tools, there must be a domain specific definition describing valid diagrams of that domain.

There are two approaches to having a domain specific diagram definition. One approach is to extend DI through MOF inheritance or package merge semantics to end up with a domain-specific DI. Although this approach benefits from having one diagram metamodel to use for each domain, it suffers from several practical drawbacks. First, it makes it more difficult to create or leverage general-purpose diagramming toolkits as it forces dealing with different possibly inconsistent diagram metamodels. Second, it reduces the potential of defining cross-domain hybrid diagrams which could undermine future integration efforts between domains. Third, it forces the resulting metamodel to have some parallel to the domain’s abstract syntax metamodel resulting in a larger interchange schema that is also more susceptible to changes to the abstract syntax metamodel, increasing the maintenance cost.

The other approach to having a domain-specific diagram definition is to define it with a separate Diagram Definition (DD) language. The metamodel for DD is used to create M1 instances (model libraries representing diagram definitions) that are referenced by diagrams (DI instances). This architecture is adopted by this specification as it allows for several advantages. First, having a domain-independent DI means the interchange schema remains small and more stable (unaffected by changes to the abstract syntax), reducing maintenance costs. Second, having domain independent DI/DD metamodels allows for creating and/or leveraging general-purpose diagramming toolkits to define DSL modeling tools with, compressing time to market. Third, having a consistent DI/DD metamodels across domains eases the integration effort between specifications and/or tools, creating synergies and increasing business value. Fourth, separating DI and DD allows better separation of concerns. While DI is used to create and persist diagrams, DD is used to define the valid diagram syntax. This increases the flexibility as it allows diagram definitions to not be restricted by MOF/schema metamodel semantics. The relationship between these various metamodel is shown in Figure 16-1, above.

The main use case for associating diagrams with their definitions, expressed as DD instances, is diagram syntax validation. The DD metamodel defines and constrains various aspects of diagrams including composition rules, semantic references, and allowed styles. The other possible use cases for diagram definition are to help automate diagram creation with proper syntax and to help query and identify various parts of diagrams in a consistent way, which helps the genericity of diagramming tools.

DD instances are called diagram definition libraries as they are defined at the M1 level. The DD library for each standard domain, like BPMN, becomes part of the specification of that domain. Such a library is published with the specification and implemented by tool vendors. (The DD library for BPMN 2.0 is defined on page 398 of this document.) Hence, the standard DD libraries referenced from user diagrams do not need to be interchanged. On the other hand, if user diagrams reference non-standard (domain extension or tool specific) DD libraries and wish to interchange with other tools, those definition libraries need to also be available and recognized by those tools; otherwise, those definitions and their data would be ignored. In any case, the diagram data is still readable as it conforms to the same non-changing DI schema.
Metamodel Description

The DD metamodel, shown in Figure 16-4, provide definitions and constraints for the artifacts in the DI metamodel. That is why there is an obvious resemblance between the designs of both metamodels. At the core of the DD metamodel, there is the concept of a view definition. A view definition specifies various aspects of how a view should conform including the type and multiplicity of child views, the definition of the allowed styles, the type of the allowed context reference and other arbitrary constraints. A view definition is further subclassed by node definition, connector definition and diagram definition to match the different kinds of views in DI. View definitions are owned by a hierarchy of nested packages.

Figure 16-4 – Diagram Definition (DD) Metamodel

Class Descriptions

NamedElement

A named element is an element with a unique name within its siblings of the same type that are contained by the same container element if any. NamedElement is an abstract metaclass.

Properties

Table 16-10 – NamedElement attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: String</td>
<td>The name of the NamedElement</td>
</tr>
</tbody>
</table>
Constraints

- The name of the element has to be unique within its siblings of the same type contained by the same container.

Package

A package is the root of containment in a DD model library that contains all view definitions in the library. It also represents a namespace for the library by having a namespace URI and a namespace prefix attributes, in addition to the name attribute inherited from NamedElement. The namespace URI uniquely identifies the package when referenced by other instance models. The namespace prefix is typically used as an alias to the URI to reduce its verbosity.

Generalizations

- NamedElement

Properties

<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>viewDefinition</code>: ViewDefinition [0..*]</td>
<td>Contains a list of view definitions in the DD instance library.</td>
</tr>
</tbody>
</table>

**ViewDefinition**

A view definition is the main abstraction in the DD metamodel. It is also the building block of a DD library. A view definition specifies the syntax rules for a view in DI. Various rules can be specified including the type and multiplicity of child views that can be composed in a view, the styles that can annotate a view, the type of the object that can be the context of a view, in addition to arbitrary constraints on a view. A view definition is abstract and is further subclassed by three concrete subclasses: diagram definition, node definition and connector definition.

The allowed context type of a view is specified by a reference to the allowed context metaclass on the view definition. When no context type is specified, a view cannot reference any context object. This is the case for purely notational views or views whose context is implied by other related views (ex. by the parent view for nodes or the source and target views for connectors). When the context type is specified, a view must reference a context object that conforms to (is instance of) this context type. For example, if a view definition references the type UML State, views conforming to this definition must reference a UML state object as a context.

The allowed styles of a view are specified by a collection of style definitions owned by the view definition. A conforming view can only be annotated by styles that conform to those style definitions. The conformance here is established when a style has the same name as well as a conforming value to one of the style definitions.

The allowed children of a view are specified by a collection of child definitions owned by the view definition. Each child definition specifies the allowed multiplicity (lower and upper bound) as well as the allowed type of a child. The type of a child definition is always a node definition. A conforming view owns children that conform to those child definitions. Child conformance is established when the child is defined by the child definition’s
type (or one of its subtypes) and respect its multiplicity (the number of children conforming to that child definition complies with its multiplicity).

A view definition can also specify arbitrary constraints on a view. Each constraint has a Boolean expression, expressed in some query language, in the context of the corresponding view’s metaclass. A constraint can check any aspect of a view including its context object, its style values and its relationships to other views. A conforming view satisfies all of its definition’s constraints.

In addition, view definitions can be defined as abstract or concrete and can be organized into inheritance hierarchies. Abstract definitions cannot be used to define views, while concrete definitions can be. To participate in an inheritance hierarchy, a view definition references another definition as its super definition. Only single inheritance is allowed for view definitions. The semantics of inheritance in this context is as follows:

- A sub view definition inherits a reference to a context type from its super definition chain. However, a sub view definition can refine the inherited context by specifying its own reference to a type that is either the same as or a subtype of the inherited context type.
- A sub view definition inherits the child definitions of its super definition chain. A sub definition can also provide its own child definitions that either add to or refine the inherited child definitions. If a new child definition has the same name as one of the inherited child definition, it is a refinement; otherwise it is an addition. A refining child definition specifies its own multiplicity and type, which is the same as or a subtype of the refined definition’s type.
- A sub view definition inherits the style definitions of its super definition chain. A sub definition can also provide its own style definitions that are additions to the inherited ones. New style definitions must have different names than the inherited definitions.
- A sub view definition inherits the constraints of its super definition chain. A sub definition can also provide its own constraints that are additions to the inherited ones. New constraints must have different names than the inherited constraints.

Generalizations

- NamedElement

Properties

**Table 16-12 – ViewDefinition attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>abstract: Boolean [0..1]</td>
<td>A Boolean value that specifies whether the view definition is abstract. The default is ‘false’ meaning non-abstract (or concrete).</td>
</tr>
<tr>
<td>package: Package</td>
<td>References the package that contains this view definition.</td>
</tr>
<tr>
<td>superDefinition: ViewDefinition [0..1]</td>
<td>References an optional super (more general) view definition of this definition.</td>
</tr>
</tbody>
</table>
### contextType: core::Class [0..1]
References an optional MOF-based metaclass representing the context type of this view definition. Views that conform to this view definition would reference a context object that is an instance of this metaclass.

### childDefinition: NodeDefinition [0..*]
Contains a list of child definitions of this view definition. Child definitions define valid children of views conforming to this view definition.

### styleDefinition: StyleDefinition [0..*]
Contains a list of style definitions of this view definition. Style definitions define valid styles of views conforming to this view definition.

### constraint: Constraint [0..*]
Contains a list of constraints of this view definition. These constraints must be satisfied by views defined by this view definition.

### Constraints
- View definition inheritance hierarchies must be directed and acyclic. A view definition cannot be both a transitively super and transitively sub definition of the same definition.
- A view definition’s context type must either be the same as or a subtype of an inherited context type.
- A view definition must have a unique name in its containing package.

### DiagramDefinition
A node definition is a concrete kind of view definition that defines the syntax rules of DI nodes.

#### Generalizations
- ViewDefinition

#### Constraints
- The super definition of a diagram definition must be of type diagram definition as well.

### NodeDefinition
A diagram definition is a concrete kind of view definition that defines the syntax rules of DI diagrams.

#### Generalizations
- ViewDefinition

#### Constraints
- The super definition of a node definition must be of type node definition as well.
**ConnectorDefinition**

A connector definition is a concrete kind of view definition that defines the syntax rules of DI connectors. A connector definition references a source view definition and a target view definition. Those definitions define the valid source and target of a connector that conforms to this connector definition.

**Generalizations**

- ViewDefinition

**Properties**

**Table 16-13 – NamedElement model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceDefinition:</td>
<td>References a view definition that defines the valid source of a connector conforming to this connector definition.</td>
</tr>
<tr>
<td>targetDefinition:</td>
<td>References a view definition that defines the valid target of a connector conforming to this connector definition.</td>
</tr>
</tbody>
</table>

**ChildDefinition**

A child definition specifies the conformance rules for child views that are contained by other views. Child definitions are owned by the view definitions of those containing views. In particular, a child definition specifies a name, inherited from NamedElement, representing a role played by conforming child views. It also specifies the valid multiplicity and type definition of those child views.

**Generalizations**

- NamedElement
Properties

Table 16-14 – ChildDefinition attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>lowerBound: Integer [0..1]</td>
<td>The lower multiplicity of child views defined by this child definition.</td>
</tr>
<tr>
<td>upperBound: Integer [0..1]</td>
<td>The upper multiplicity of child views defined by this child definition.</td>
</tr>
<tr>
<td>typeDefinition: NodeDefinition</td>
<td>References a node definition that defines the child view.</td>
</tr>
<tr>
<td>parentDefinition: ViewDefinition</td>
<td>References a view definition that contains this child definition.</td>
</tr>
</tbody>
</table>

Constraints

- A child definition must have a unique name within its containing view definition.

StyleDefinition

A style definition is contained by a view definition. It specifies the conformance rules of a style that can annotate views that conform to that view definition. In particular, a style definition specifies a name, which needs to match a style’s name to establish the correspondence between them. A style definition also specifies the type that a style value needs to conform to. This type is one of the primitive types (i.e. not structured type). A default value can also be specified.

Additionally, a style definition specifies whether a style is inherited or not. An inherited style allows views that are not annotated themselves with this style to “inherit” the style from the closest parent that is annotated with this style in their parent chain.
Properties

Table 16-15 – StyleDefinition attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>default: String [0..1]</td>
<td>An optional default value of the style.</td>
</tr>
<tr>
<td>inherited: Boolean[0..1]</td>
<td>Specifies whether the style is inherited or not. The default is ‘false’, i.e. not inherited.</td>
</tr>
<tr>
<td>type: core::PrimitiveType</td>
<td>References the MOF-based primitive type of this style</td>
</tr>
<tr>
<td>viewDefinition: ViewDefinition</td>
<td>References a view definition that contains this style definition.</td>
</tr>
</tbody>
</table>

Constraint

A constraint represents an arbitrary condition expressed in some query language that must be satisfied by views conforming to the view definition that contains this constraint. The context type of a constraint corresponds to the view metaclass implied by the view definition that owns the constraint.

Generalizations

- NamedElement

Properties

Table 16-16 – Constraint attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>

Annex C

(Informative)

Glossary

[The Glossary has been taken from the BPMN 1.1 specification and needs to be updated.]

A

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activity:</td>
<td>An activity is a generic term for work that company or organization performs via business processes. An activity can be atomic or non-atomic (compound). The types of activities that are a part of a Process Model are: Process, Sub-Process, and Task.</td>
</tr>
<tr>
<td>AND-Join:</td>
<td>(from the WfMC Glossary) An AND-Join is a point in the Process where two or more parallel executing activities converge into a single common thread of Sequence Flow. See “Join.”</td>
</tr>
<tr>
<td>AND-Split:</td>
<td>(from the WfMC Glossary) An AND-Split is a point in the Process where a single thread of Sequence Flow splits into two or more threads which are executed in parallel within the Process, allowing multiple activities to be executed simultaneously. See “Fork.”</td>
</tr>
<tr>
<td>Artifact:</td>
<td>An Artifact is a graphical object that provides supporting information about the Process or elements within the Process. However, it does not directly affect the flow of the Process. BPMN has standardized the shape of a Data Object. Other examples of Artifacts include critical success factors and milestones.</td>
</tr>
<tr>
<td>Association:</td>
<td>An Association is a dotted graphical line that is used to associate information and Artifacts with Flow Objects. Text and graphical non-Flow Objects can be associated with the Flow Objects and Flow.</td>
</tr>
<tr>
<td>Atomic Activity:</td>
<td>An atomic activity is an activity not broken down to a finer level of Process Model detail. It is a leaf in the tree-structure hierarchy of Process activities. Graphically it will appear as a Task in BPMN.</td>
</tr>
</tbody>
</table>

5The underlined terms in this definition were changed from the original definition. “Process” is used in place of “workflow,” “Sequence Flow” is used in place of “control.”
**Business Analyst:** A Business Analyst is an individual within an organization who defines, manages, or monitors Business Processes. They are usually distinguished from the IT specialists or programmers who implement the Business Process within a BPMS.

**Business Process:** TBD.

**Business Process Management:** Business Process Management (BPM) encompasses the discovery, design, and deployment of business processes. In addition, BPM includes the executive, administrative, and supervisory control of those processes.\(^6\)

**BPM System:** The technology that enables BPM.

**Choreography:** Choreography is an ordered sequence of B2B message exchanges.

**Collaboration:** Collaboration describes interactions between two or more PartnerEntities or PartnerRoles.

**Collaboration Process:** A Collaboration Process depicts the interactions between two or more business entities.

**Collapsed Sub-Process:** A Collapsed Sub-Process is a Sub-Process that hides its flow details. The Collapsed Sub-Process object uses a marker to distinguish it as a Sub-Process, rather than a Task. The marker is a small square with a plus sign (+) inside.

**Compensation Flow:** Compensation Flow is defines the set of activities that are performed during the roll-back of a transaction to compensate for activities that were performed during the Normal Flow of the Process.

Compensation can also be called from a Compensate End or Intermediate Event.

**Compound Activity:** A compound activity is an activity that has detail that is defined as a flow of other activities. It is a branch (or trunk) in the tree-structure hierarchy of Process activities. Graphically, it will appear as a Process or Sub-Process in BPMN.

---

**Controlled Flow:** Flow that proceeds from one Flow Object to another, via a Sequence Flow link, but is subject to either conditions or dependencies from other flow as defined by a Gateway.

Typically, this is seen as a Sequence flow between two activities, with a conditional indicator (mini-diamond) or a Sequence Flow connected to a Gateway.

**Decision:** Decisions are locations within a business process where the Sequence Flow can take two or more alternative paths. This is basically the “fork in the road” for a process. For a given performance (or instance) of the process, only one of the forks can be taken. A Decision is a type of Gateway. See “Or-Split.”

**End Event:** As the name implies, the End Event indicates where a process will end. In terms of Sequence Flow, the End Event ends the flow of the Process, and thus, will not have any outgoing Sequence Flow. An End Event can have a specific Result that will appear as a marker within the center of the End Event shape. End Event Results are Message, Error, Compensation, Link, and Multiple. The End Event shares the same basic shape of the Start Event and Intermediate Event, a circle, but is drawn with a thick single line.

**Event Context:** An Event Context is the set of activities that can be interrupted by an exception (Intermediate Event).

This can be one activity or a group of activities in an expanded Sub-Process.

**Exception:** An Exception is an event that occurs during the performance of the process that causes Normal Flow of the process to be diverted exclusively from Normal Flow. Exceptions can be generated by a time out, fault, message, etc.

**Exception Flow:** Exception Flow is a set of Sequence Flow that originates from an Intermediate Event that is attached to the boundary of an activity. The Process will not traverse this flow unless an Exception occurs during the performance of that activity (through an Intermediate Event).

**Expanded Sub-Process:** An Expanded Sub-Process is a Sub-Process that exposes its flow detail within the context of its Parent Process. It will maintain its rounded rectangle shape, but
Proposal for: 501 Business Process Model and Notation (BPMN), v2.0

Flow: A Flow is a graphical line connecting two objects in a BPMN diagram. There are two types of Flow: Sequence Flow and Message Flow, each with their own line style. Flow is also used in a generic sense (and lowercase) to describe how Tokens will traverse Sequence Flow from the Start Event to an End Event.

Flow Object: A Flow Object is one of the set of following graphical objects: Events, Activities, and Gateways.

Fork: A fork is a point in the Process where a single flow is divided into two or more Flow. It is a mechanism that will allow activities to be performed concurrently, rather than sequentially. BPMN uses multiple outgoing Sequence Flow or a Parallel Gateway to perform a Fork. See “AND-Split.”

Intermediate Event: An Intermediate Event is an event that occurs after a Process has been started. It will affect the flow of the process, but will not start or (directly) terminate the process. An Intermediate Event will show where messages or delays are expected within the Process, disrupt the Normal Flow through exception handling, or show the extra flow required for compensating a transaction. The Intermediate Event shares the same basic shape of the Start Event and End Event, a circle, but is drawn with a thin double line.

Join: A Join is a point in the Process where two or more parallel Sequence Flow are combined into one Sequence Flow. BPMN uses an Parallel Gateway to perform a Join. See “AND-Join.”

Lane: An Lane is a sub-partition within a Pool and will extend the entire length of the Pool, either vertically or horizontally. Lanes are used to organize and categorize activities within a Pool. The meaning of the Lanes is up to the modeler.

Merge: A Merge is a point in the process where two or more alternative Sequence Flow are combined into one.
Sequence Flow. BPMN uses multiple incoming Sequence Flow or an Exclusive Gateway to perform a Merge. See “OR-Join.”

**Message:**
A Message is the object that is transmitted through a Message Flow. The Message will have an identity that can be used for alternative branching of a Process through the Event-Based Exclusive Gateway.

**Message Flow:**
A Message Flow is a dashed line that is used to show the flow of messages between two entities that are prepared to send and receive them. In BPMN, two separate Pools in the Diagram will represent the two entities.

**Normal Flow:**
Normal Flow is the flow that originates from a Start Event and continues through activities via alternative and parallel paths until it ends at an End Event.

**OR-Join:**
(from the WfMC Glossary[7]) An OR-Join is a point in the Process where two or more alternative activity(s) Process branches re-converge to a single common activity as the next step within the Process. (As no parallel activity execution has occurred at the join point, no synchronization is required.) See “Merge.”

**OR-Split:**
(from the WfMC Glossary[1]) An OR-Split is a point in the Process where a single thread of Sequence Flow makes a decision upon which branch to take when encountered with multiple alternative Process branches. See “Decision.”

**Parent Process:**
A Parent Process is the Process that holds a Sub-Process within its boundaries.

**Participant:**
A Participant is a Partner Entity (e.g., a company, company division, or a customer) or a Partner Role (e.g., a buyer or a seller), which controls or is responsible for a business process. If Pools are used, then a Participant would be represented by a Pool.

**Pool:**
A Pool represents a Participant in a Process. It also acts as a “swimlane” and a graphical container for partitioning a set of activities from other Pools, usually in the context of B2B situations. It is a square-cornered rectangle that

---

7The underlined terms in this definition were changed from the original definition. “Process” is used in place of “workflow.” “Sequence Flow” is used in place of “control.”
is drawn with a solid single line. A Pool acts as the container for the Sequence Flow between activities. The Sequence Flow can cross the boundaries between Lanes of a Pool, but cannot cross the boundaries of a Pool. The interaction between Pools, e.g., in a B2B context, is shown through Message Flow.

**Private Process:** A private Process is internal to a specific organization and is the type of process that has been generally called a workflow or BPM Process. There are two (2) types of private Processes: executable and non-executable. A single executable private Process will map to a single BPEL document.

**Process:** A Process is any activity performed within a company or organization. In BPMN a Process is depicted as a network of Flow Objects, which are a set of other activities and the controls that sequence them.

**Public Process:** A Public Process represents the interactions between a private Business Process and another Process or Participant.

**Result:** A Result is consequence of reaching an End Event. Results can be of different types, including: Message, Error, Compensation, Link, and Multiple.

**Sequence Flow:** A Sequence Flow is a solid graphical line that is used to show the order that activities will be performed in a Process. Each Flow has only one source and only one target.

**Start Event:** A Start Event indicates where a particular Process will start. In terms of Sequence Flow, the Start Event starts the flow of the Process, and thus, will not have any incoming Sequence Flow. A Start Event can have a Trigger that indicates how the Process starts: Message, Timer, Rule, Link, or Multiple. The Start Event shares the same basic shape of the Intermediate Event and End Event, a circle, but is drawn with a single thin line.

**Sub-Process:** A Sub-Process is Process that is included within another Process. The Sub-Process can be in a collapsed view that hides its details. A Sub-Process can be in an expanded view that shows its details within the view of the Process in which it is contained. A Sub-Process shares the same shape as the Task, which is a rectangle that has rounded corners.
Swimlane: A Swimlane is a graphical container for partitioning a set of activities from other activities. BPMN has two different types of Swimlanes. See “Pool” and “Lane.”

Task: A Task is an atomic activity that is included within a Process. A Task is used when the work in the Process is not broken down to a finer level of Process Model detail. Generally, an end-user and/or an application are used to perform the Task when it is executed. A Task object shares the same shape as the Sub-Process, which is a rectangle that has rounded corners.

Token: A Token is a descriptive construct used to describe how the flow of a process will proceed at runtime. By tracking how the Token traverses the Flow Objects, gets diverted through alternative paths, and gets split into parallel paths, the normal Sequence Flow should be completely definable. A Token will have a unique identity that can be used to separate multiple Tokens that may exist because of concurrent process instances or the splitting of the Token for parallel processing within a single process instance.

Transaction: A Transaction is a set of coordinated activities carried out by independent, loosely-coupled systems in accordance with a contractually defined business relationship. This coordination leads to an agreed, consistent, and verifiable outcome across all participants.

Trigger: A Trigger is a mechanism that signals the start of a business process. Triggers are associated with a Start Events and Intermediate Events and can be of the type: Message, Timer, Rule, Link, and Multiple.

Uncontrolled Flow: Flow that proceeds, unrestricted, from one Flow Object to another, via a Sequence Flow link, without any dependencies on another flow or any conditional expressions. Typically, this is seen as a Sequence flow between two activities, without a conditional indicator (mini-diamond) or any intervening Gateway.
